On Saturday, Feb. 8th, the Countess of Aberdeen journeyed from Dublin to Banbridge, county Down, to open the Tuberculosis Exhibition which is being held there. In the Temperance Hall, where the exhibition is located, lectures were given by Her Excellency, by Mr. R. Martin (medical officer of health of Banbridge), Dr. W. Chancellor, and others. In the evening Sir John Byers gave the opening lecture on "What We May Observe in the Tuberculosis Exhibition." The subsequent lecturers were the Registrar-General (Sir Robert Matheson), Professor E. J. McWeeney, Dr. W. Calwell, Dr. H. L. McKisack, and Dr. R. T. Herron.

The Lady Superintendent of the Belfast Workhouse.

The Local Government Board has refused to approve of the appointment of a lady elected by the Belfast board of guardians as lady superintendent of the workhouse and training school for nurses, having regard to the deliberate statements of the visiting medical officers and to the fact that, in the opinion of the Local Government Board, she does not possess the necessary personal qualifications for the office. Accordingly it recommended the guardians to proceed to another election. In reply, the guardians have requested the Local Government Board to sanction the appointment for a probationary period of six months. The Local Government Board has written refusing to sanction such an appointment on probation and advised the Belfast guardians again to proceed to a new appointment, but at their weekly meeting on Jan. 28th the guardians, by 17 votes to 15, decided that the letter of the Local Government Board should be sent to a committee (which was subsequently appointed) with instructions to reply to it and to advance reasons in favour of the appointment.

The Risks of Arsenic in Agriculture.

AT a meeting of the Academy of Medicine held on Jan. 28th M. Cazeneuve called the attention of his audience to a situation which has become extremely alarming. Within the last two or three years enormous quantities of arsenic have been used in agricultural operations. The employment of this poison by the vine-growers is no new thing in France, for it was suggested some 12 years ago as a means of combating insect pests, but its use has greatly increased in recent years. By far the greater part of the arsenic employed comes from a Spanish mining district. In 1901 this district supplied 120 tons of arsenical ores, while in 1905 the quantity necessary for agricultural needs had risen to 4810 tons. Arsenic is not only employed in viticulture but also used for diseases of olives, and various instances of fatal poisoning have occurred in animals that have fed under the olive trees. At the conclusion of his address M. Cazeneuve asked the Academy to point out the dangers which might arise from the indiscriminate use of arsenic.

Immediate Operation in Gunshot Wounds of the Auditory Region.

At a meeting of the Paris Hospitals Internes' Society held on Jan. 23rd M. Wicart insisted on the necessity for immediate operation in gunshot wounds of the auditory region. He based his remarks upon many cases which he had seen and on one in particular where radiography had not revealed the site of the ball which in consequence had not been extracted. Chronic suppuration set in, facial paralysis became incurable, and labyrinthine trouble persisted. The best route to follow for extractions was the retro-auricular, and the clearing out of the petro-mastoid cavity would be found to be of great assistance.[1]

The Treatment of Old-standing Injuries of the Wrist by Total Resection of the Carpus.

At a meeting of the Surgical Society held on Jan. 29th M. Valas read a paper on this subject. He said that traumatic lesions of the wrist in which efforts at reduction have failed are often capable of being greatly improved by immediate operation and sometimes even by massage alone; when, however, the lesions are of old standing, whether on account of having been overlooked or because immediate treatment has failed, they cause such inconvenience that the patient is always anxious that something should be done to help him. The majority of surgeons content themselves with removing the dislocated or fractured bones, but this method of operating generally means that successive operations have to be performed until all the carpal bones have been taken away. M. Valas therefore considers it better to remove the whole carpus at one sitting. In six cases which he has treated in this way he has obtained excellent results; in all these cases the carpal lesion was at least four months old and all the patients recovered complete movement of the hand. M. Valas concluded by saying that he thought that complete resection of the wrist was an excellent plan to adopt in such cases as he had described.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Surgical Treatment of Bronchiectasis.

Professor Koerte recently read a paper before the Berlin Medical Society on Operations for Bronchiectasis. He pointed out the difficulty of surgical intervention because in bronchiectasis a great number of cavities without a direct communication are usually present. The diagnosis was also very difficult, especially as regards the difference between bronchiectasis and gangrene of the lung. The operations for pulmonary gangrene gave, as a rule, better results than operations for bronchiectasis, for Professor Koerte has lost only eight out of 28 patients operated on for gangrene, as compared with 11 deaths in 15 operations for bronchiectasis. The only cases suitable for operation were those in which the bronchiectasis was limited to one lobe of a lung. A resection of at least two ribs was essential to make the lung accessible. After the lung was incised each bronchiectasis must individually be opened, tied, and plugged. If the cavity did not collapse after the operation an extensive resection must be carried out. The dangers of the operation consisted in the profuse hæmorrhage and in the shock which might occur at the moment of the incision. He did not use Sauerbruch's chamber for the operation but he avoided pneumothorax by drawing the lung quickly into the wound. The early cases gave the best results but they, of course, very seldom presented themselves for surgical treatment.

Diabetes Conjugalis.

At a recent meeting of the Berlin Medical Society Professor Senator discussed the question whether diabetes might be communicated from husband to wife and *vice versâ.* He said that some writers, believing that the disease *can be so* communicated, have proposed the name of "diabetes conjugalis" for this condition. Dr. Schmitz of Neuenahr had found 26 married couples among 2320 diabetic patients, being 1·1 per cent. of the total number. The computation ought, however, to be made not by comparing the diabetic couples with the total diabetics, but by comparing the diabetic couples with the diabetic patients who were either married or lived connubially. The proportion of diabetic are municipal health regulations on a par with those of any town in England) it can be carried to a fine art. Milk-sellers, for example, are as a rule unable to refrain from watering their milk and this is accepted by the foreign community (as they and not the Chinese are milk-drinkers) as so inevitable that the chief growl is about the quality of the water more than the quantity of it. Some Chinese dairymen, however, carry the adulteration to a high pitch of excellence and add a yellow-coloured emulsion of beef tallow to liberally watered milk. When this emulsion dissolves out it rises as a rich thick cream, out of which butter can be made. If some of this cream be added to boiling water the tallow congeals on cooling—a rough-and-ready test which is but rarely employed.

Jan. 8th.

Obituary.

WILLIAM ALLINGHAM, F.R.C.S. ENG.,

CONSULTING SURGEON TO THE GREAT NORTHERN CENTRAL HOSPITAL.

THE death of Mr. William Allingham, which we have already announced as having taken place at Worthing on Feb. 4th, was not unexpected, for his health had been very unsatisfactory for some time, while he had reached the advanced age of 78 years.

William Allingham was born in 1829 and received his early education with architecture as its object. He studied his art at University College, London, took several students' prizes in the subject, and later, while practising his first profession, exhibited studies at the exhibitions of the Royal Academy and obtained an honourable mention for a design which he submitted for a building to house the Great Exhibition of 1851. In this same year, however, he decided to abandon his profession and turned to medicine, which had always attracted him. He entered as a student at St. Thomas's Hospital and had a successful career, taking prizes in anatomy, systematic and clinical medicine, and the Treasurer's prize—in fact, he secured most of the rewards that fall to the lot of the able and energetic student. In 1855 he became a Member of the Royal College of Surgeons, proceeding to the Fellowship two years later, while between the taking of his pass and honour diploma he had the valuable and honourable experience of serving as surgeon in the Crimean war. He volunteered as soon as he was qualified and reached the seat of war, which was then in progress, in time to be present at the siege of Sebastopol and to see a vast amount of practical surgery in the most arduous circumstances at the hospitals at Scutari. During a large part of his war services he was attached to the French army, which was extremely badly provided with surgical aid, and there is no doubt that under the strenuous nature of the duties which devolved upon him Allingham gained the courage and sense of responsibility which marked him out as a successful operating surgeon from the beginning of his career. On his return he was for a time surgical tutor and demonstrator of anatomy and later surgical registrar at St. Thomas's Hospital, and in 1863 he commenced practice as a consulting surgeon in Finsbury-square, then a very favourite centre for consulting practice. In a very short time he became known as a specialist in diseases of the rectum, and in 1873 he published his well-known book on that subject. This book went through five editions, the last one appearing in 1888; it was translated into several foreign languages and was accepted generally as an authoritative and inclusive work, though several surgeons differed from the author on points of operative procedure and technique. The work took final shape in 1901 when Herbert Allingham, William Allingham's eldest son, collaborated with his father in an edition so thoroughly revised as to be practically rewritten.

As he became more successful Allingham, following the example of other well-known consultants, transferred his practice from Finsbury-square to Grosvenor-street, and during the whole of the later period of his professional career he enjoyed a large practice as a consulting surgeon in cases of diseases of the rectum. He came to be regarded as one of the first authorities on the subject as well as one of the most skilful operators where surgical measures had to be taken. Although he was never on the honorary staff of one of the great metropolitan hospitals possessing a medical school, he was for many years surgeon to the Great Northern Central Hospital and to St. Mark's Hospital for Fistula and Diseases of the Rectum, while he was also consulting surgeon to the Farringdon General Dispensary and to the Surgical Aid Society, with the founding of which society in 1862 he was intimately connected. In 1884 he was elected on the Council of the Royal College of Surgeons of England. He retired from practice in 1894.

Allingham, who was widely known in private life as a most kindly, generous man, an excellent host, and a sympathetic friend, was twice married. His first wife was Miss Christiana Hooke, by whom he had six children, the eldest son being Herbert Allingham, the brilliant young surgeon whose untimely death will be fresh in the memory of our readers; while both his daughters married medical men, the elder, now Mrs. Chevallier Tayler, the wife of the well-known artist, having married first Mr. Charles Cotes whose memory as a surgical tutor is still preserved among St. George's men; while the younger is the wife of Mr. Claud E. Woakes. Allingham married secondly Miss D. H. Hayles who predeceased him last year and by whom he had no children.

HERMANN SNELLEN, M.D.,

PROFESSOR OF OPHTHALMOLOGY, UNIVERSITY OF UTRECHT.

THE death of Professor Snellen of Utrecht removes another of the few remaining links with the founders of modern ophthalmology. The seed sown by Donders, von Graefe, and von Helmholtz fell upon fertile soil and was worthily tended by illustrious disciples. The mantle of Donders fell upon Snellen who has borne it nobly through a long and strenuous career.

Hermann Snellen was born in 1834, the son of Dr. F. A. Snellen, a well-known physician. He studied at Utrecht, where he remained as student and professor throughout his life. His graduation thesis presented in 1857 gave ample evidence of his perseverance and skill in original research and of that scientific imagination which can alone guide research into fruitful paths. It was published in Virchow's *Archiv* in 1858 and dealt with neuroparalytic keratitis. In attacking this subject Snellen was entering the lists with those whose names were most famous in physiology, such as Magendie, Claude Bernard, Kühne, Gaule, Schiff, and others. He was led by his experiments to bring forward the simplest theory which could be held to explain the condition. He regarded neuroparalytic keratitis as a purely traumatic condition, the severity of which was due to the anæsthesia of the cornea, whereby slight injuries, such as those caused by foreign bodies, failed to set in motion those reflex acts which are nature's method of relief. The theory brought into prominence factors which had been overlooked or under-estimated by his predecessors and if it cannot be credited as a complete solution of the problem it was a stride towards that solution which after 50 years' interval we still await. In 1862 Snellen was appointed lecturer in ophthalmology and surgeon to the Dutch Hospital for Diseases of the Eye at Utrecht. In the same year he published those test types which have since been employed universally. Test types had already been devised by Küchler (1843), Jaeger (1854), Stellwag von Carion (1855), and others, but it was not until 1862 that they were devised upon a scientific basis simultaneously and independently by Snellen and Giraud-Teulon at an ophthalmic congress in Paris. The basis was a visual angle of one minute and Snellen's types are constructed on the principle that each letter subtends a visual angle of five minutes at the nodal point of the eye when placed at the given distance from the eye, whilst the breadth of the individual lines which compose the letter subtends an angle of one minute at the nodal point. Innumerable varieties of test types have since been brought forward, but the fundamental principle, being founded upon accurate physiological data, is universally maintained. Snellen's test types for near vision, constructed upon the same lines, have not found the same favour as his distant types, for in the circumstances in which they are employed other factors which tend to vitiate their accuracy come into play.

Though doubtless influenced greatly by his master Donders and by that mathematical instinct which is strongly developed in so many Dutch men of science, Snellen did not confine his attention to optics. He devoted much time and thought to the relief of deformities of the lids, and "Snellen's sutures" are familiar to every ophthalmologist to-day. Indeed, he made his mark in every department of ophthalmology. For many years he was associated with Leber, who

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Water-supply of Medina.

ON previous occasions[1] I have given some accounts of the recent measures undertaken to supply Mecca with drinkable water. The sister city Medina, quite or nearly as sacred to Islam as Mecca, on the good water-supply of which many thousands of Moslem pilgrims so much depend, is also soon to receive proper canalisation works and every other requisite for a large and satisfactory provision of pure water. The Sultan has already given the necessary orders to proceed, with as little delay as possible, with the construction of these canalisation works. There is, I understand, a copious supply of water conducted from a tepid source at the village of Kuba, two miles south of Medina, and distributed in underground cisterns in each quarter. Besides, a number of torrent courses (of which the Kanat to the north, at the foot of Mount Ohod, and Akik, some miles to the south, are the most important) descend from the mountains, forming considerable streams and pools after rain. These torrent courses, which converge in the neighbourhood of the city at a place called Zaghaba, make the whole district for many miles around one of the best watered spots in Northern Arabia. There is also underground water which can be reached by sinking deep wells, but many of these wells are brackish and quite useless for drinking purposes. Through the suburbs of Medina, which are the quarters of the peasants, runs the watercourse of the Batan, a tributary of the Kanat. All these water sources have been used for many centuries for drinking and cooking purposes. As some of the wells are of considerable depth the so-called "sakkas" (water carriers) descend into them with the help of ladders and after filling their "courbas" (leather bags) with water distribute it to the various houses. Seeing that these wells and other sources are quite open to all sorts of pollution and contamination, this mode of supplying water to the inhabitants of Medina left much to be wished for. The population continually suffered from different gastric troubles and infectious diseases, such as enteric fever, which have naturally been attributed to the contamination of the water. The water to be canalised is that of Zerka, or Aini Zerka. It will be conducted into two great reservoirs of 2000 cubic metres capacity. From these reservoirs the water will be conveyed into smaller reservoirs and fountains to be erected at different places in the city. All the works of canalisation will be constructed under the direction of a special commission. The way in which wells are dug at Medina is interesting. First a well is opened at a high elevation, then another lower down, a third still lower, and so on. Afterwards all these wells, from the highest to the lowest, are connected by subterranean channels. In this manner the water is brought to a plane whence it is conveyed to different points of the city and its suburbs. Often the inhabitants united of their own accord to execute these works. The two above-mentioned great reservoirs will be constructed upon the place called Menahe situated in the north of Medina.

Feb. 7th.

NOTES FROM PEKING.

(FROM OUR OWN CORRESPONDENT.)

The Opium Question.

IN spite of all that has passed on the subject of opium in China, from Imperial edicts against the trade down to missionary and lay protests, the question still remains in a most unsettled and unsatisfactory condition. A new phase has recently been entered upon by the action of the Viceroy of Nanking who proposes to establish a Government monopoly in the opium business in his capital, a step that would no doubt be extended to other parts of the province if successful in Nanking. This has caused a strong protest from the British firms concerned in the foreign opium trade who feel their business would be injured unjustly, as it is not a matter concerning the use of opium but merely of diverting it into Chinese hands, thus infringing established treaty rights. The Hong-Kong Chamber of Commerce has taken the matter in hand and is upholding the merchants' appeal to the Governor to see that the monopoly is not allowed. There is evidence to prove that the sale of anti-opium pills (containing a percentage of opium) and morphine is increasing. While the foreign importation of opium is decreasing the area under poppy cultivation is being extended and the native article is also improving in quality. Those of us who have an opportunity of judging can see little if any diminution in the number of Chinese addicted to the habit, though certain high officials have found themselves compelled to give it up. In the meantime one may rest content that the British and Chinese Governments are taking a right view of the whole matter, especially in the light of the recent agreements that there is to be a gradual diminution of the Indian opium trade *pari passu* with the decrease in the production of the native drug. This will not content the extremists among the anti-opium advocates but the moderates will realise that a sound incentive is given to China to make serious efforts to diminish her own output.

Climate and Health.

During the winter months (October to February inclusive) there is a great diminution of bacterial diseases. In the absence of sanitary regulations the public health may be looked upon as very good. With the exception of sporadic cases of small-pox all zymotic diseases die down and the chief complaints among hospital patients are rheumatism, neuralgia, bronchitis, and conjunctivitis, the two last being mostly due to noxious fumes of anthracite stoves in houses which have no chimneys. Not infrequently one meets with cases of gangrene of the toes in the old and poor and a curious feature is the large number of workmen out-patients who suffer from septic inflammation of the hands due to cracks and fissures in callosities through which dirt enters. A good many Europeans also suffer from fissures at the points of the fingers due to the extreme dryness of the atmosphere and low temperature which at present ranges from 10° F. at night to 32° by day. The prevailing wind is north and north-west and as it comes from over the steppes of Siberia and Mongolia it is bitterly cold and sometimes accompanied by clouds of fine dust. The sky is, as a rule, cloudless and the sun often genially warm, so that one may look upon the winter climate of North China as being on the whole a very healthy one. With the exception of occasional visits of influenza (from one of which we are now suffering) the European population enjoys good health. Children thrive well and there is no need here for that separation from their parents which has been found necessary in South China and India; indeed, there are a good many European adults in North China who have never been home and yet are found healthy specimens of manhood. Fog or mist is unknown. Notwithstanding the healthiness of the climate the tuberculous rate suffers little diminution and still awaits the time when Chinese "enlightenment," which is so much talked about at present, reaches that stage when public health regulations will be found necessary to deal with the high mortality rate in this disease.

Small-pox.

The beginning of every winter sees a recrudescence of this disease and it is generally supposed that the removal by the Chinese of their winter clothes from the pawnshops has much to do with the annual visitation. These garments consist of two layers of cotton between which is a thick layer of cotton-wool. Though in North China inoculation is still practised to some extent it has been of late years supplemented by calf lymph, a good supply of which has been imported from Japan. Here and there throughout Peking are Government vaccination stations where those who care to submit themselves can be vaccinated without any regard to asepsis. An increasing number are availing themselves of the facilities offered. It is not an uncommon sight to see blind men with deeply pock-marked faces feeling their way through the streets.

Adulteration of Milk.

In the absence of any legislation against adulteration (except in a foreign settlement such as Shanghai where there

---

[1] THE LANCET, August 4th and Nov. 3rd, 1906.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: APPOINTMENT OF CONSERVATOR.—At an ordinary monthly meeting of the Council of the Royal College of Surgeons held on Thursday last Dr. Arthur Keith, lecturer on anatomy and curator of the museum at the London Hospital, was appointed Conservator of the museum of the College.

THE ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—His Majesty the King has recently caused ten brace of pheasants and his annual subscription of £10 10*s.* to be forwarded to the Royal Waterloo Hospital, S.E. This institution was founded in 1816 by the late Queen Victoria's father, H.R.H. the Duke of Kent.

PRESENTATION TO A MEDICAL PRACTITIONER.—On Feb. 6th the chief constable of Exeter, on behalf of the members of the Exeter police force, presented Mr. Joseph Anthony Wenceslaus Pereira, M.D. Brux., L.R.C.P. Lond., M.R.C.S. Eng., with a portrait of himself as a mark of appreciation of his services to the force.

ASHTON INFIRMARY.—The District Infirmary, Ashton-under-Lyne, was founded in 1860 and since that time has been endowed with £64 478. The annual meeting of the subscribers was held on Feb. 1st and the familiar story told that more help was required, as the present income would not suffice for present wants, while the claims on the institution were always increasing. The deficit on general purposes was £1696 and the extension fund account was overdrawn by £1099, making a total of £2795. The chairman said that "the hospital was almost exclusively carried on for the benefit of the working people and he appealed to that class for increased help." An interesting part of the proceedings was an address by the Hon. Miss Brodrick who was a nurse at the infirmary two years ago.

ST. PETERSBURG PSYCHO-NEUROLOGICAL INSTITUTE.—The *Novoe Vremya* says that the Psycho-Neurological Institute, organised by Professor Bechtereff and involving an expenditure of £80,000, is about to begin work. The governing idea of the promoter is the "scientific observation of psychic and nerve diseases uninterruptedly and over a long series of years, as far as possible in the same patient, so that an ideal patient for the institute would be a child whose growth, development, and life would furnish to the observer a complete biography in the form of a living picture. Specialists in many aspects of human life, besides medical men, will use the institute, so that patients may be studied from every point of view." The institute is on ground belonging to the Military Medical Academy but is under the control of the Ministry of Public Education.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next quarterly meeting of this association will take place, by the courtesy of Dr. A. Miller, at the Warwick County Asylum, Hatton, on Thursday, Feb. 20th, at 3 o'clock, under the presidency of Dr. P. W. MacDonald. Dr. John Turner will give a lantern demonstration and read a paper upon Some Further Observations bearing on the Supposed Thrombotic Origin of Epileptic Fits. Dr. R. Cunyngham Brown will read a paper entitled "The Boarding-out of the Insane in Private Dwellings," which will be illustrated by lantern views. Dr. Miller invites members to luncheon at the Hatton Asylum at 1.30 P.M. and it is requested that an early reply may be sent to him. Members will dine together at 7 o'clock at the Regent Hotel, Leamington, and will entertain some distinguished guests from the neighbourhood. It is hoped that as many members as possible will be present at the dinner. Evening dress is optional.

BRITISH MEDICAL ASSOCIATION: AWARD OF THE MIDDLEMORE PRIZE.—At the recent meeting of the Council of the British Medical Association the Middlemore Prize was awarded to Mr. Simeon Snell, F.R.C.S. Edin., for his contributions to the science of ophthalmology. This prize is of the value of £50, together with an illuminated scroll, and was founded by the late Richard Middlemore, ophthalmic surgeon of Birmingham, who bequeathed a sum of money for an award to be made every third year for the best essay on the scientific and practical value of improvements in ophthalmic medicine and surgery made or published during the previous three years. By a supplemental deed it was provided that the award might be made for the best essay or work on any subject in any department of ophthalmology. Mr. Simeon Snell is President-elect of the British Medical Association and the prize will be handed to him at the forthcoming annual meeting at Sheffield in July next.

DEATH OF A CENTENARIAN.—Mrs. Mary Davies of Ystradmynach died recently at the age of 104 years.

THE STATE REGISTRATION OF NURSES.—A public meeting in support of the State registration of trained nurses will be held at the Caxton Hall, Westminster, S.W., on Friday, Feb. 21st, at 3 P.M. The chair will be taken by the Lady Helen Munro Ferguson.

DONATIONS AND BEQUESTS.—The late Mr. Thomas Hawley of Coventry by will bequeathed £500 to the Barnardo Homes, and a similar sum to the Leamington Hospital for Incurables.—By the will of Mrs. Mary Berrey of St. Leonards, Sussex, £1000 are bequeathed to the Beau Site Convalescent Home, Hastings, and a like sum to the Royal Society for Incurables, Putney.—During 1907 the employees of Messrs. J. S. Fry and Sons voluntarily collected £632 for the Bristol medical charities.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Industrial Poisoning.

A COPY of the preliminary tables of cases of industrial poisoning, fatal and non-fatal accidents, and dangerous occurrences in factories and workshops during the year 1907 has been presented to Parliament in pursuance of the Factory and Workshop Act, 1901, and the Notice of Accidents Act, 1906.

National Physical Laboratory.

The report of the Committee appointed by the Treasury to inquire generally into the work now performed at the National Physical Laboratory has been laid on the table of the House of Commons.

The Children Bill.

Several of the provisions of the Children Bill which Mr. H. SAMUEL, the Under Secretary for the Home Department, introduced into the House of Commons on Monday are of special interest to the medical profession. The measure is of a consolidating as well as of an amending nature. For example, it re-enacts the Infant Life Protection Bill of 1897, which was passed to stop the evils of baby-farming and to protect the lives of infants sent out to nurse. That Act has been found ineffective and the Government proposes that a Select Committee should examine the subject and submit conclusions to the House so to enable them to be included in the Bill in its later stages. The Bill further proposes to deal with the evil of the overlying of infants. Mr. SAMUEL stated that over 1600 infants a year met their death by overlying and that this waste of life might be prevented. The Government proposes that a penalty should be imposed in such cases. The offence is not one of wilful cruelty but of negligence, and the penalty will be a light one except in cases where drunkenness can be proved. A penalty is also proposed in cases where children meet their death by scalds and burns received through having been left alone in a room with unguarded fires.

The evil of smoking by juveniles is at last to be tackled, and no part of the Bill was received with more applause than that in which the Government proposes to put a stop to the practice, so far as is possible, by legislation. The Bill prohibits the sale of cigarettes, or of cigarette papers, to young persons under the age of 16. It further prohibits these young persons from smoking in streets and public places, and makes them liable to a reprimand for the first offence and to a light fine for subsequent infringements of the law in this respect. A still more effective provision of the Bill places in the hands of the police and of other authorised persons the power to confiscate the tobacco which is being used by these youthful smokers in the streets. The Home Office has also under consideration a plan to deal with automatic machines for the sale of cigarettes, but Mr. SAMUEL, whose remarks were circumscribed by the operation of the "ten minutes' rule," did not mention the lines on which the department proposed to proceed in this matter. The Bill, which is very comprehensive in its scope, contains clauses for the establishment of children's courts and for the separation of the child offender from the ordinary adult criminal. The proposal further is to abolish the imprisonment of children and young persons up to the age of 16 years with a few carefully designed and necessary exemptions. A most favourable reception was given to the Bill which was read a first time.

Infant Life Protection Bill.

Mr. STAVELEY HILL'S Bill to amend the Infant Life Protection Act of 1897 has been published. The object of the Bill is to extend the provisions of the Act to cases where only one child is taken in to be

Deputies. Those of the profession in the British Isles who can take their holiday during the month of May—always delightful in Italy—might do worse than honour the "Riunione" with their presence.

(FROM OUR OWN CORRESPONDENT.)

The Opium Question.

IN spite of all that has passed on the subject of opium in China, from Imperial edicts against the trade down to missionary and lay protests, the question still remains in a most unsettled and unsatisfactory condition. A new phase has recently been entered upon by the action of the Viceroy of Nanking who proposes to establish a Government monopoly in the opium business in his capital, a step that would no doubt be extended to other parts of the province if successful in Nanking. This has caused a strong protest from the British firms concerned in the foreign opium trade who feel their business would be injured unjustly, as it is not a matter concerning the use of opium but merely of diverting it into Chinese hands, thus infringing established treaty rights. The Hong-Kong Chamber of Commerce has taken the matter in hand and is upholding the merchants' appeal to the Governor to see that the monopoly is not allowed. There is evidence to prove that the sale of anti-opium pills (containing a percentage of opium) and morphine is increasing. While the foreign importation of opium is decreasing the area under poppy cultivation is being extended and the native article is also improving in quality. Those of us who have an opportunity of judging can see little if any diminution in the number of Chinese addicted to the habit, though certain high officials have found themselves compelled to give it up. In the meantime one may rest content that the British and Chinese Governments are taking a right view of the whole matter, especially in the light of the recent agreements that there is to be a gradual diminution of the Indian opium trade *pari passu* with the decrease in the production of the native drug. This will not content the extremists among the anti-opium advocates but the moderates will realise that a sound incentive is given to China to make serious efforts to diminish her own output.

Climate and Health.

During the winter months (October to February inclusive) there is a great diminution of bacterial diseases. In the absence of sanitary regulations the public health may be looked upon as very good. With the exception of sporadic cases of small-pox all zymotic diseases die down and the chief complaints among hospital patients are rheumatism, neuralgia, bronchitis, and conjunctivitis, the two last being mostly due to noxious fumes of anthracite stoves in houses which have no chimneys. Not infrequently one meets with cases of gangrene of the toes in the old and poor and a curious feature is the large number of workmen out-patients who suffer from septic inflammation of the hands due to cracks and fissures in callosities through which dirt enters. A good many Europeans also suffer from fissures at the points of the fingers due to the extreme dryness of the atmosphere and low temperature which at present ranges from 10° F. at night to 32° by day. The prevailing wind is north and north-west and as it comes from over the steppes of Siberia and Mongolia it is bitterly cold and sometimes accompanied by clouds of fine dust. The sky is, as a rule, cloudless and the sun often genially warm, so that one may look upon the winter climate of North China as being on the whole a very healthy one. With the exception of occasional visits of influenza (from one of which we are now suffering) the European population enjoys good health. Children thrive well and there is no need here for that separation from their parents which has been found necessary in South China and India; indeed, there are a good many European adults in North China who have never been home and yet are found healthy specimens of manhood. Fog or mist is unknown. Notwithstanding the healthiness of the climate the tuberculous rate suffers little diminution and still awaits the time when Chinese "enlightenment," which is so much talked about at present, reaches that stage when public health regulations will be found necessary to deal with the high mortality rate in this disease.

Small-pox.

The beginning of every winter sees a recrudescence of this disease and it is generally supposed that the removal by the Chinese of their winter clothes from the pawnshops has much to do with the annual visitation. These garments consist of two layers of cotton between which is a thick layer of cotton-wool. Though in North China inoculation is still practised to some extent it has been of late years supplemented by calf lymph, a good supply of which has been imported from Japan. Here and there throughout Peking are Government vaccination stations where those who care to submit themselves can be vaccinated without any regard to asepsis. An increasing number are availing themselves of the facilities offered. It is not an uncommon sight to see blind men with deeply pock-marked faces feeling their way through the streets.

Adulteration of Milk.

In the absence of any legislation against adulteration (except in a foreign settlement such as Shanghai where there

---

[1] THE LANCET, August 4th and Nov. 3rd, 1903.

My attention has been called to the subject referred to in it and in September last I caused a circular to be issued to local authorities bringing the matter under their notice in order that they might, as far as possible, exercise supervision over the cattle in their districts with a view to anticipating and so averting possible or intended infringement of the law. I also suggested that suitable officers of the local authority should be instructed to watch closely the cattle markets, slaughter-houses, and knackers' yards in the district, with the view of satisfying themselves that no animal, the condition of which appears to render it unfit for human consumption, is disposed of in such a manner that it is likely to be used for this purpose.

The Death-rate in Britain and Germany.

Mr. HADDOCK asked the President of the Local Government Board what was the reduction in the death-rate in Germany and the United Kingdom between the years 1870 and 1906.—Mr. BURNS furnished the following written reply: The Registrar-General's figures for England and Wales only give the death-rates for the German Empire from 1872 onwards. I have thought it better, therefore, to compare the quinquennia 1872–76 and 1901–05 and the single years 1872 and 1905:—

Percentage reduction in death-rate between—	United Kingdom.	German Empire.
	Per cent.	Per cent.
(1) 1872–76 and 1901–05	23	28
(2) 1872 and 1905	26	32

It should be added that, although the German death-rate has declined to a greater extent than the English death-rate, it remains (in 1905) 19·8 per 1000 of population, as against 15·5 per 1000 in the United Kingdom. In other words, the death-rate of Germany in 1905 was 28 per cent. higher than that of the United Kingdom.

WEDNESDAY, FEB. 12TH.

The Midwives Act.

Mr. ROGERS asked the President of the Local Government Board whether he had considered the provisions of the Midwives Act, 1902, which forbids the practice, habitually and for gain, of midwifery after Jan. 1st, 1910, by any woman not certified under the Act; whether he was aware that much doubt existed whether it would be found possible then and in future for trained certified midwives to earn an adequate livelihood by the practice of their profession in rural districts where population and births were few in number; and whether, in view of the importance of proper care for mother and child and the close proximity of the date after which unskilled attendance was forbidden, he was prepared to introduce further legislation charging the supervising authorities, as created by the Act of 1902, with the duty and the power of securing for all cases of childbirth within their area such efficient nursing as the Act requires, but for which no provision was made.—Mr. BURNS replied: The attention of the Government has been called to this matter, which is primarily one for the Lord President of the Council. I understand that the whole subject is receiving his consideration and that he is in communication with the Central Midwives Board with regard to it.

BOOKS, ETC., RECEIVED.

AMERICAN OPHTHALMOLOGICAL SOCIETY, Hartford. (Secretary, Dr. S. B. St. John, 26, Pratt-street, Hartford, Conn., U.S.A.).

occupies a similar position with regard to von Graefe that Snellen does to Donders, and others in editing the chief German ophthalmic journal, von Graefe's *Archiv für Ophthalmologie*. Many of his original communications are contained in that journal. With Professor Landolt he is responsible for the article upon Ophthalmometrology in the first edition of the "Graefe-Saemisch Handbuch der gesammten Augenheilkunde." He wrote the chapter on the Methods of Determining the Acuity of Vision in "Norris and Oliver's System of Diseases of the Eye," an essay on the Development of our Knowledge of Glaucoma in the *Ophthalmic Review* (1881), &c. Snellen was appointed to the chair of ophthalmology in the University of Utrecht in 1877; he resigned in 1899, when he was succeeded by his son Hermann Snellen, junior.

We are indebted to Mr. E. Nettleship for the following remarks: "I first saw Snellen about 1872 or 1873 when he was in London; I was curator of the Moorfields Museum, only just commencing ophthalmic work, and beyond a general impression that he was a learned but very accessible man nothing remains. In the early 'eighties' I went to Holland for a short time, taking Utrecht first, and well remember the warmth and cordiality with which my wife and I were received at his house and that of Professor Donders, to whom he introduced us. Snellen paid frequent visits to Great Britain; he spoke English fluently and was a genuine admirer of many things English. He was intensely national in spirit and expressed the strongest dislike to the possibility of his country being absorbed into the German Empire. Snellen was a most genial, kindly, warm-hearted man, of the simplest habits, and intensely fond of his large family. He was a striking personality—large-framed, tall, with handsome features, and especially fine eyes, which though usually mild in expression could show animation and intense fire on occasion. Of placid temper, he had the gift of never fussing or seeming hurried, but of never being too late, and he carried his quiet energy and methodical thoroughness into his professional work. His operative manner and method were, I thought, equal to the best, although I remember thinking his desire for improvement sometimes led him to try new modes, especially of dressing after operation, rather readily, and always to think the newest plan the best."

ROBERT BIRCH, L.R.C.P. LOND., M.R.C.S. ENG., L.S.A.

Mr. Robert Birch of Newbury, who died on Jan. 24th, was formerly one of the principal practitioners in the town, but the state of his health unfortunately compelled him to relinquish active work some years ago and he had for a long time been a confirmed invalid. He was born in 1850 at Lichfield in Staffordshire, where his father was a solicitor. He studied medicine at King's College and was admitted a Licentiate of the Society of Apothecaries in 1871; in 1873 he took the diplomas of L.R.C.P. Lond. and M.R.C.S. Eng. He went to Newbury in 1876 and entered into partnership with the late Dr. Ryott. When the Newbury district hospital was established in 1885 he joined the medical staff, and on resigning his position in 1898 on the ground of ill-health he was elected one of the consulting medical officers. He was for a time a member of the Newbury town council and filled several other offices of local importance, having been a commissioner of taxes and librarian of the literary and scientific institution. He was one of the founders of the Newbury and District Medical Society, of which he was afterwards honorary secretary and president. Mr. Birch was married in 1882, and besides a widow he has left four sons and one daughter. The body was cremated at Woking on Jan. 25th.

FREDERICK MORITZ SYKES, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

THE death of Mr. Frederick Moritz Sykes occurred after a short illness at his residence, the Manor House, Bridlington, on Feb. 7th. The deceased, who was a native of Clitheroe, studied at Edinburgh, and after qualifying there and also obtaining the Licence of the Glasgow Faculty made a voyage to the Amazon. In 1894 he went to Bridlington where he entered into partnership with Dr. T. Thompson, with whom he carried on a very extensive practice up to 1900, when his partner left the town in consequence of failing health. Thereafter, Mr. Sykes undertook the entire conduct of the practice alone. He was a member of the honorary medical staff of the Lloyd Hospital. From the first he was exceedingly popular and was held in great esteem by all classes of the community.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. G. Levy, formerly physician of the Civil Hospital of Strasburg.—Dr. T. Lemberger, *privat-docent* of pharmacology in the University of Cracow.

Medical News.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.—At examinations held in February for the Diploma in Public Health the following candidates were successful:—

Martha Adams, M.B. Glasg.; Robert Muschamp, L.R.C.P. & S. Edin.; and John James Scanlan, L.R.C.P. & S. Edin.

APOTHECARIES' HALL OF IRELAND.—At a special meeting of the court held on Feb. 3rd the following candidates having passed the necessary examinations were admitted Licentiates in Medicine, Surgery, Midwifery, and Pharmacy of the Apothecaries' Hall of Ireland:—

Synott Valentine O'Connor and John Hargreaves Robinson.

FOREIGN UNIVERSITY INTELLIGENCE.—*Budapest:* Dr. Frans Pcór has been recognised as *privat-docent* of Dermatology and Dr. Kornél Scholtz as *privat-docent* of Ophthalmology.—*Heidelberg:* Dr. Carl Menge of Erlangen has been appointed Professor of Midwifery and Gynæcology in succession to Professor von Rosthorn.—*Kieff:* Dr. F. Stefanis, Extraordinary Professor of Anatomy, has been appointed Ordinary Professor.—*Philadelphia:* Dr. B. F. Stahl has been appointed Professor of Medicine and Dr. M. B. Hartzell Professor of Dermatology in the Woman's Medical College of Pennsylvania, and Dr. J. H. Gibbon Professor of Surgery in the Jefferson Medical College.—*Pisa:* Dr. G. Gonella of Cagliari has been appointed to the chair of Ophthalmology.—*Toronto:* Dr. Charles K. Clarke has been appointed to the chair of Psychiatry.

LITERARY INTELLIGENCE.—The Oxford University Press will publish immediately the Fitz-Patrick lectures delivered before the Royal College of Physicians of London by Dr. Norman Moore, under the title "The History of the Study of Medicine in the British Isles." The volume contains numerous illustrations.

CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH AT BUXTON.—A congress of the Royal Institution of Public Health will take place at Buxton from July 18th to 24th under the presidency of the Right Honourable Victor Cavendish, M.P. An exhibition of medical and sanitary equipments, appliances relating to school hygiene, and gas, water, and electrical apparatus will be held in the fine corridor of the Buxton Pavilion (352 feet long), and will be open to the public. The honorary secretaries of the exhibition are Mr. J. W. Souden and Mr. W. J. Leeming, Electricity Works, Buxton.

UNREGISTERED DENTISTS.—At a meeting recently held at Torquay of the registered dental practitioners of Torquay and Paignton the following motion was carried:—

> That in view of the rapidly increasing number of unregistered persons practising dentistry and evading the Dental Act of 1878, we appeal to all registered dental surgeons throughout the country to use their utmost endeavour by local combination to assist the authorities in taking steps to amend the Act and whenever possible to bring forward cases to enable them to take action.

The following resolution has been signed and sent to the General Medical Council:—

> We the undersigned registered dental surgeons in practice in Torquay and Paignton, S. Devon, desire to draw your attention to the urgent need for some action to be taken to check the increasing evil of unregistered persons practising dentistry and evading the Dentists Act of 1878. During the past two years ten or more unregistered persons have started practice in these towns and the vicinity and we feel it is quite time that something should be done for our protection. (Signed)—Torquay: J. R. Andrews, F. N. Codrington Butler, Frank Briggs, J. Garnet Hemsted, Alfred Hunt, H. Helyar, T. S. Kendell, L. Strangways, J. Glanville Turle, and Rupert Wheatley. Paignton: C. B. Grenville, William Foot, James Petherbridge, and W. R. Whelock.

Notes, Short Comments, and Answers to Correspondents.

MISAPPLIED INGENUITY.

Two men are said to have purchased 38 pound packages of margarine with a quarter of a pound of butter at 10*d.* The police stated that the quarter of a pound of butter had been cut into small pieces, one of which had been put on the end of the pound packages of margarine, so that intending customers could then taste the genuine 10*d.* butter without coming to the margarine. One of the men went into a small shop in Blackburn, posing as a farmer whose milk float had broken down, and asked the shopkeeper if she would take a pound of butter at 1*s.* She took it, but as it was a little short of weight she received 1*d.* back. The men pleaded guilty and were sent to prison for three months. This will give them time to think over, and perhaps to improve on, their plans. It is a pity that so much ingenuity should take such an abnormal twist.

PRECAUTIONS IN DISPENSING POISONOUS LINIMENTS AND APPLICATIONS TO HOSPITAL PATIENTS.

To the Editor of THE LANCET.

SIR,—A distressing case of poisoning by misadventure has recently come under my observation in which a hospital patient, 76 years of age, took some aconite, belladonna, and chloroform liniment in mistake for a dose of medicine with fatal results, in spite of the fact that the liniment was dispensed in a fluted poison bottle, distinctly labelled *poison, for external use only.* This very forcibly impresses upon me the necessity of safeguarding the public as far as possible against such mishaps by a further precaution—that is, using a metal sprinkler instead of an ordinary cork for such bottles, which method would serve two useful purposes. In the first place it cannot be removed from the bottle without attracting the attention of children or persons who cannot read or in the case of a person under the influence of drink or distracted with pain. And in the second place it would insure economy in using the liniment which is a distinct consideration for those engaged in hospital dispensing, and although many suggestions have been made from time to time to make poison bottles more distinctive none appears to me so practical as using a sprinkler instead of an ordinary cork. Some years ago a similar fatality occurred with an out-patient of a London hospital, but in that instance the belladonna liniment was dispensed in an ordinary eight-ounce medicine bottle. I am, Sir, yours faithfully,

J. A. THOMAS, M.P.S.

General Hospital, Cheltenham, Feb. 8th, 1907.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY. (*Pathological Section*). 8.30 P.M., Discussion on Acidosis in Pregnancy (opened by Dr. J. B. Leathes). Dr. Spriggs and Dr. Bainbridge will continue the discussion. The Obstetric Section of the Royal Society of Medicine is especially invited.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—9 P.M., Mr. C. J. Symonds: Tuberculosis of the Kidney (illustrated by lantern slides, cases, and specimens). (Second Lettsomian Lecture.)

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 20, Hanover-square, W.

FRIDAY.—8.30 P.M., Fleet-Surgeon P. W. Bassett-Smith: Kala Azar in the Royal Navy (*with illustrative cases*). Sir Patrick Manson: A Case of Kala Azar ending in Recovery. Dr. J. Cropper: Phenomenal Abundance of Malarial Parasites in the Peripheral Circulation from a Case of Pernicious Malaria in the Jordan Valley.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN, 11, Chandos street, Cavendish-square, W.

FRIDAY.—5 P.M., Dr. G. Carpenter, Dr. E. Cautley, Dr. Whipham, Dr. P. Parkinson, Mr. G. Pernet, Mr. M. Yearsley, Mr. S. Stephenson, and others: Cases. Mr. H. S. Clogg: A Case of Intestinal Obstruction, Resection of a Foot of Gangrenous Intestine, Recovery.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Mr. C. L. Curties and Mr. J. E. Barnard Exhibitions of Slides and Lamp. Mr. E. M. Nelson: Eye-pieces for the Microscope. Rev. E. Tozer: The Life History of a New Protophyte. Mr. F. Chapman: On Dimorphism in the Recent Foraminifer, Alveolina Boscii.

CHELSEA CLINICAL SOCIETY, Chelsea Dispensary, Manor-street, Chelsea, S.W.

TUESDAY.—8.30 P.M., Mr. C. English: The Quiescent Appendix. Dr. T. W. Parkinson: Contrast of Symptoms in Two Cases of Cancer of the Pancreas.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MONDAY, WEDNESDAY, AND FRIDAY.—5 P.M., Prof. V. Bonney: A Study of the Connective Tissues in Carcinoma and in certain Pathological Conditions preceding its Onset.
(Hunterian Lectures.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Dr. J. M. H. MacLeod: Lupus Erythematosus.

TUESDAY.—4 P.M., Dr. W. Harris: Clinique (Medical). 5.15 P.M., Dr. M. C. Hawkes: Swedish Medical Gymnastics, their Application in the Treatment of Diseases of the Nervous System.

WEDNESDAY.—4 P.M., Mr. J. Pardoe: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. Mackenzie: The Nature of the Symptoms in Heart Failure.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. T. W. Eden: The Examination of Pregnant Women before Labour.

FRIDAY.—4 P.M., Mr. A. Lawson: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—12 noon, Lecture:—Dr. Low: Pathological. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Dr. Davis: Clinical.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12 noon: Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Moullin: Gynæcological Cases.

WEDNESDAY.—10 A.M., Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Dr. Pritchard: On the Vaccination Treatment of Infective Diseases.

THURSDAY.—12 noon, Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Edwards: Clinical.

nursed or maintained in consideration of a sum of money paid down. The Bill further enables the local authority to remove an infant kept by a person who is unfit by character or otherwise to have his or her care or maintenance or who is in a house unsuitable for the purpose. This subject is also dealt with in the Children Bill.

Dairies (Scotland) Bill.

A Bill has been introduced into the House of Commons by Mr. GULLAND for the purpose of regulating dairies in Scotland and insuring the purity of milk-supplies.

HOUSE OF LORDS.

TUESDAY, FEB. 11TH.

Milk Legislation.

The Earl of NORTHBROOK asked the President of the Board of Agriculture whether it was the intention of the Government to introduce legislation with regard to the milk supply during the present session; and, in the event of such legislation being introduced by the Local Government Board, what steps the Board of Agriculture proposed to take for the purpose of safeguarding the interests of agriculture.

Earl CARRINGTON said that, as had been announced in the House of Commons, it was the intention of the Government to introduce legislation this session with regard to milk-supply. He admitted that the present control of the milk industry was not at all in as satisfactory condition as could be wished. The Board of Agriculture was anxious to do everything it possibly could to put the industry on a safer and more satisfactory basis. As regarded the second part of the question the Government could not be expected to make a definite announcement until the proposals were a little more developed. He would do all he could legitimately to protect farmers consistently with the public interest.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 5TH.

Moisture in Irish Butter.

Mr. RICHARDSON asked the honourable Member for South Somerset, as representing the President of the Board of Agriculture, what labelling would be necessary for Irish butter sold to the public which might contain more than 16 per cent. of moisture and up to 24 per cent. of moisture.—Sir EDWARD STRACHEY replied: The Board has no authority to determine the manner in which Irish butter containing more than 16 per cent. of water should be sold so as to avoid giving rise to a complaint by the purchaser under the Sale of Food and Drugs Acts and it is not desirable that it should express an opinion on the question.

A Case of Anthrax.

Sir FRANCIS CHANNING asked the Secretary of State for the Home Department whether an inquiry had been, or would be, made into the death by anthrax in the Royal Albert Hospital, Devonport, of John Tidds, a labourer, who had recently been employed in unloading a steamer which arrived from Karachi with a cargo of grain; and whether, having regard to occasional cases of infection from handling cargoes of hides, wool, and other articles from abroad, representations by circular, and in British possessions by regulations, had been, or would be, made and communicated to foreign shippers, British consuls, and officials to secure better precautions against infection.—Mr. GLADSTONE furnished the following written reply: Inquiries have been made by the factory inspector of the district and the certifying surgeon into this case. It appears that the man had been engaged in the hold of the vessel handling bags containing Karachi barley and it is suggested by the certifying surgeon that the infection was conveyed by the sacks. A danger of this kind is obviously one that is very difficult to guard against. The Home Office has circulated cautionary notices for posting in premises where infected material is likely to be handled, and has also, through the Foreign Office, circulated widely to our consuls abroad copies of a series of lectures on anthrax which were delivered some little time ago by the medical inspector of factories. It is difficult to see what further steps can be taken until the advance of scientific inquiry discloses new methods of detecting the danger and new precautions that may be taken to meet it.

THURSDAY, FEB. 6TH.

The Administration of the Vaccination Act, 1907.

Mr. LLOYD MORGAN asked the Secretary of State for the Home Department whether when declarations were made by conscientious objectors under the Vaccination Act, 1907, before a justice of the peace without going to petty sessions a fee of 1s. had to be paid by the person making the declaration; and whether the justice of the peace before whom the declaration was made was obliged to demand the payment of the fee and pay it over to the county fund as a clerk's fee.—Mr. GLADSTONE replied: A fee authorised by a table of justices' clerk's fees can be demanded only when a clerk has rendered the service in respect of which the fee is authorised. I am advised that when a declaration is made before a justice in the absence of a clerk no fee should be demanded.

Mr. BLACK asked the President of the Local Government Board whether he was aware that vaccination officers in some parts of the country were not sending the parents of unvaccinated and unexempted children the notice "Q" before those children reached the age of four months; and whether he would issue a special circular to all vaccination officers reminding them of their duty in this respect, so that those parents who were still unaware of the provisions of the Act of 1907 might have time to acquaint themselves with the present state of the law before it was too late for them to make a declaration of conscientious objection when they wished to do so, but were unaware of the time limit.—Mr. BURNS replied: I have not received the complaint that vaccination officers in any part of the country are not sending the notice referred to. Their duty in the matter was pointed out in a circular issued to the guardians last year, a copy of which I requested might be given to each vaccination officer. It does not seem necessary to issue another circular; but if my honourable friend is aware of any case in which the vaccination officer has omitted to serve the notice, and if he will give me the particulars of it, I will make inquiry with regard to it. I may add that in consequence of orders which I have caused to be issued the parent is made acquainted with the provisions of the new Vaccination Act at the time when the birth of the child is registered. These orders have been in force since September last.

Mr. CROOKS asked the President of the Local Government Board whether his attention had been called to difficulties that had arisen in obtaining the benefits of the Vaccination Act, 1907, in cases where the father of a child had been personally precluded from making a statutory declaration in consequence of absence from England on business as a sailor or otherwise at the time of the birth of his child and for the four months afterwards allowed by the Act in which the statutory declaration was to be made; and whether he would consider the advisability of taking steps, by legislation or otherwise, to enable in such circumstances the wife to make the necessary statutory declaration under the provisions of Section 35 of the Vaccination Act, 1867, in the absence of her husband.—Mr. BURNS replied by written answer: My attention has been called to difficulties of the kind mentioned since the passing of the Act of last session. The law officers advised in 1893 that, in ordinary circumstances, the father was the only person who could obtain a certificate of conscientious objection, and a similar view would no doubt apply to the making of a declaration under the recent Act. I am not empowered to decide whether, in circumstances such as those mentioned in the question, the mother would be the person competent to make the declaration; but it seems to me that, if she did so, proceedings ought not to be taken against the father.

FRIDAY, FEB. 7TH.

Medical Appointments in the Territorial Force.

Mr. CROOKS asked the Secretary of State for War whether it was proposed to appoint Surgeon-Lieutenant-Colonel (Honorary Surgeon-Colonel) P. B. Giles, one of the medical officers of the First Herefordshire Rifle Volunteers, to the office of principal medical officer of one of the London divisions of the Territorial Army, who did not reside in London; and, if any question of seniority of commission was concerned in the appointment, whether such a principle of selection had been adopted in connexion with similar appointments to other divisions of the Territorial Army.—Mr. HALDANE furnished the following written reply: It is proposed to appoint this officer as stated in the question. He is commandant of the Volunteer Ambulance School in London, an institution which has been most successful in training a large proportion of volunteer medical officers. He resides near London. Seniority was not the determining factor in selecting officers for the appointment mentioned in the question, but those officers best fitted to carry out the work were chosen, seniority being given its due weight.

MONDAY, FEB. 10TH.

The Medical Inspection of School Children.

Mr. WEDGWOOD asked the President of the Board of Education whether his attention had been called to the speech of the chairman of the Staffordshire education committee in which he stated that the efficiency or otherwise with which the local authorities put into operation the medical inspection of school children would be a determining factor in the annual grant given by the Board of Education; whether this was generally known by all local education authorities; and whether the Board would circularise authorities, stating at the same time that it considered the appointment of whole-time medical men, as in Staffordshire, to be the surest way of securing this efficiency.—Mr. MCKENNA replied: The Board has stated in section 10 of the Memorandum on Medical Inspection which has been issued to all local education authorities that the effectiveness of the minimum inspection required under the Act will in future be one of the elements to be considered in determining the efficiency of each school as a grant-aided school. The appointment of whole-time medical officers will no doubt be advisable in larger and more populous districts, but in view of the differences in area and population among the various local education authorities who are charged with the duties of inspection, I do not think an expression of opinion such as my honourable friend suggests could be made of universal or even of general application. The Board will always be happy to give advice to any authority which desires to consult it, but the detailed arrangements and *personnel* required will be matters in the first instance for the consideration of the authority in the light of local circumstances and existing public health organisation.

Mr. MACKARNESS asked the President of the Board of Education whether he had considered the additional expense likely to be thrown upon the local authorities by carrying out the medical inspection of children under Section 13 of the Education Administrative Provisions) Act, 1907; and whether it was proposed to give them any relief from the Imperial Exchequer.—Mr MCKENNA answered: The financial arrangements in connexion with the forthcoming Education Bill will include an additional grant in aid of expenses of local education authorities under Part III. of the Act.

Expenditure on Vaccination.

Answering Mr. LUPTON,

Mr. BURNS said that the total expenditure by boards of guardians on vaccination in 1905 was £275,828 and in 1906 £260,295. The total expenditure for 1907 was not yet completely ascertained.

TUESDAY, FEB. 11TH.

The Royal Commission on the Feeble-Minded.

In answer to Mr. WEDGWOOD, Sir HENRY CAMPBELL-BANNERMAN said that the chairman of the Royal Commission on the Feeble-Minded had informed him that the report of the Commission, which was in an advanced condition, had recently been delayed by unforeseen circumstances, but it was confidently hoped that it would be completed before Easter.

The Sale of Tuberculous Cattle.

Mr. CATHCART WASON asked the honourable Member for South Somerset, as representing the President of the Board of Agriculture, whether he was aware that cattle in the last stages of tuberculosis were occasionally exposed for sale and food in the open market with consequent risk of spread of the disease and danger to human life; and whether he proposed to take any steps, by legislation or otherwise, in order that persons submitting dying diseased cattle for sale might be prosecuted.—Mr. BURNS sent the following written reply: My honourable friend has asked me to reply to this question.

Notes, Short Comments, and Answers to Correspondents.

MISAPPLIED INGENUITY.

Two men are said to have purchased 38 pound packages of margarine with a quarter of a pound of butter at 10*d*. The police stated that the quarter of a pound of butter had been cut into small pieces, one of which had been put on the end of the pound packages of margarine, so that intending customers could then taste the genuine 10*d*. butter without coming to the margarine. One of the men went into a small shop in Blackburn, posing as a farmer whose milk float had broken down, and asked the shopkeeper if she would take a pound of butter at 1*s*. She took it, but as it was a little short of weight she received 1*d*. back. The men pleaded guilty and were sent to prison for three months. This will give them time to think over, and perhaps to improve on, their plans. It is a pity that so much ingenuity should take such an abnormal twist.

PRECAUTIONS IN DISPENSING POISONOUS LINIMENTS AND APPLICATIONS TO HOSPITAL PATIENTS.

To the Editor of THE LANCET.

SIR,—A distressing case of poisoning by misadventure has recently come under my observation in which a hospital patient, 76 years of age, took some aconite, belladonna, and chloroform liniment in *mistake for a dose of medicine with fatal results, in spite of the fact* that the liniment was dispensed in a fluted poison bottle, distinctly labelled *poison, for external use only*. This very forcibly impresses upon me the necessity of safeguarding the public as far as possible against such mishaps by a further precaution—that is, using a metal sprinkler instead of an ordinary cork for such bottles, which method would serve two useful purposes. In the first place it cannot be removed from the bottle without attracting the attention of children or persons who cannot read or in the case of a person under the influence of drink or distracted with pain. And in the second place it would insure economy in using the liniment which is a distinct consideration for those engaged in hospital dispensing, and although many suggestions have been made from time to time to make poison bottles more distinctive none appears to me so practical as using a sprinkler instead of an ordinary cork. Some years ago a similar fatality occurred with an out-patient of a London hospital, but in that instance the belladonna liniment was dispensed in an ordinary eight-ounce medicine bottle. I am, Sir, yours faithfully,

J. A. THOMAS, M.P.S.

General Hospital, Cheltenham, Feb. 8th, 1907.

A Case of Anthrax.

Sir FRANCIS CHANNING asked the Secretary of State for the Home Department whether an inquiry had been, or would be, made into the death by anthrax in the Royal Albert Hospital, Devonport, of John Tidds, a labourer, who had recently been employed in unloading a steamer which arrived from Karachi with a cargo of grain; and whether, having regard to occasional cases of infection from handling cargoes of hides, wool, and other articles from abroad, representations by circular, and in British possessions by regulations, had been, or would be, made and communicated to foreign shippers, British consuls, and officials to secure better precautions against infection.—Mr. GLADSTONE furnished the following written reply: Inquiries have been made by the factory inspector of the district and the certifying surgeon into this case. It appears that the man had been engaged in the hold of the vessel handling bags containing Karachi barley and it is suggested by the certifying surgeon that the infection was conveyed by the sacks. A danger of this kind is obviously one that is very difficult to guard against. The Home Office has circulated cautionary notices for posting in premises where infected material is likely to be handled, and has also, through the Foreign Office, circulated widely to our consuls abroad copies of a series of lectures on anthrax which were delivered some little time ago by the medical inspector of factories. It is difficult to see what further steps can be taken until the advance of scientific inquiry discloses new methods of detecting the danger and new precautions that may be taken to meet it.

THURSDAY, FEB. 6TH.

The Administration of the Vaccination Act, 1907.

Mr. LLOYD MORGAN asked the Secretary of State for the Home Department whether when declarations were made by conscientious objectors under the Vaccination Act, 1907, before a justice of the peace without going to petty sessions a fee of 1s. had to be paid by the person making the declaration; and whether the justice of the peace before whom the declaration was made was obliged to demand the payment of the fee and pay it over to the county fund as a clerk's fee.—Mr. GLADSTONE replied: A fee authorised by a table of justices' clerk's fees can be demanded only when a clerk has rendered the service in respect of which the fee is authorised. I am advised that when a declaration is made before a justice in the absence of a clerk no fee should be demanded.

Mr. BLACK asked the President of the Local Government Board whether he was aware that vaccination officers in some parts of the country were not sending the parents of unvaccinated and unexempted children the notice "Q" before those children reached the age of four months; and whether he would issue a special circular to all vaccination officers reminding them of their duty in this respect, so that those parents who were still unaware of the provisions of the Act of 1907 might have time to acquaint themselves with the present state of the law before it was too late for them to make a declaration of conscientious objection when they wished to do so, but were unaware of the time limit.—Mr. BURNS replied: I have not received the complaint that vaccination officers in any part of the country are not sending the notice referred to. Their duty in the matter was pointed out in a circular issued to the guardians last year, a copy of which I requested might be given to each vaccination officer. It does not seem necessary to issue another circular; but if my honourable friend is aware of any case in which the vaccination officer has omitted to serve the notice, and if he will give me the particulars of it, I will make inquiry with regard to it. I may add that in consequence of orders which I have caused to be issued the parent is made acquainted with the provisions of the new Vaccination Act at the time when the birth of the child is registered. These orders have been in force since September last.

Mr. CROOKS asked the President of the Local Government Board whether his attention had been called to difficulties that had arisen in obtaining the benefits of the Vaccination Act, 1907, in cases where the father of a child had been personally precluded from making a statutory declaration in consequence of absence from England on business as a sailor or otherwise at the time of the birth of his child and for the four months afterwards allowed by the Act in which the statutory declaration was to be made; and whether he would consider the advisability of taking steps, by legislation or otherwise, to enable in such circumstances the wife to make the necessary statutory declaration under the provisions of Section 35 of the Vaccination Act, 1867, in the absence of her husband.—Mr. BURNS replied by written answer: My attention has been called to difficulties of the kind mentioned since the passing of the Act of last session. The law officers advised in 1898 that, in ordinary circumstances, the father was the only person who could obtain a certificate of conscientious objection, and a similar view would no doubt apply to the making of a declaration under the recent Act. I am not empowered to decide whether, in circumstances such as those mentioned in the question, the mother would be the person competent to make the declaration; but it seems to me that, if she did so, proceedings ought not to be taken against the father.

FRIDAY, FEB. 7TH.

Medical Appointments in the Territorial Force.

Mr. CROOKS asked the Secretary of State for War whether it was proposed to appoint Surgeon-Lieutenant-Colonel (Honorary Surgeon-Colonel) P. B. Giles, one of the medical officers of the First Herefordshire Rifle Volunteers, to the office of principal medical officer of one of the London divisions of the Territorial Army, who did not reside in London; and, if any question of seniority of commission was concerned in the appointment, whether such a principle of selection had been adopted in connexion with similar appointments to other divisions of the Territorial Army.—Mr. HALDANE furnished the following written reply: It is proposed to appoint this officer as stated in the question. He is commandant of the Volunteer Ambulance School in London, an institution which has been most successful in training a large proportion of volunteer medical officers. He resides near London. Seniority was not the determining factor in selecting officers for the appointment mentioned in the question, but those officers best fitted to carry out the work were chosen, seniority being given its due weight.

MONDAY, FEB. 10TH.

The Medical Inspection of School Children.

Mr. WEDGWOOD asked the President of the Board of Education whether his attention had been called to the speech of the chairman of the Staffordshire education committee in which he stated that the efficiency or otherwise with which the local authorities put into operation the medical inspection of school children would be a determining factor in the annual grant given by the Board of Education; whether this was generally known by all local education authorities; and whether the Board would circularise authorities, stating at the same time that it considered the appointment of whole-time medical men, as in Staffordshire, to be the surest way of securing this efficiency.—Mr. MCKENNA replied: The Board has stated in section 10 of the Memorandum on Medical Inspection which has been issued to all local education authorities that the effectiveness of the minimum inspection required under the Act will in future be one of the elements to be considered in determining the efficiency of each school as a grant-aided school. The appointment of whole-time medical officers will no doubt be advisable in larger and more populous districts, but in view of the differences in area and population among the various local education authorities who are charged with the duties of inspection, I do not think an expression of opinion such as my honourable friend suggests could be made of universal or even of general application. The Board will always be happy to give advice to any authority which desires to consult it, but the detailed arrangements and *personnel* required will be matters in the first instance for the consideration of the authority in the light of local circumstances and existing public health organisation.

Mr. MACKARNESS asked the President of the Board of Education whether he had considered the additional expense likely to be thrown upon the local authorities by carrying out the medical inspection of children under Section 13 of the Education Administrative Provisions) Act, 1907; and whether it was proposed to give them any relief from the Imperial Exchequer.—Mr. MCKENNA answered: The financial arrangements in connexion with the forthcoming Education Bill will include an additional grant in aid of expenses of local education authorities under Part III. of the Act.

Expenditure on Vaccination.

Answering Mr. LUPTON,

Mr. BURNS said that the total expenditure by boards of guardians on vaccination in 1905 was £275,828 and in 1906 £260,295. The total expenditure for 1907 was not yet completely ascertained.

TUESDAY, FEB. 11TH.

The Royal Commission on the Feeble-Minded.

In answer to Mr. WEDGWOOD, Sir HENRY CAMPBELL-BANNERMAN said that the chairman of the Royal Commission on the Feeble-Minded had informed him that the report of the Commission, which was in an advanced condition, had recently been delayed by unforeseen circumstances, but it was confidently hoped that it would be completed before Easter.

The Sale of Tuberculous Cattle.

Mr. CATHCART WASON asked the honourable Member for South Somerset, as representing the President of the Board of Agriculture, whether he was aware that cattle in the last stages of tuberculosis were occasionally exposed for sale and food in the open market with consequent risk of spread of the disease and danger to human life; and whether he proposed to take any steps, by legislation or otherwise, in order that persons submitting dying diseased cattle for sale might be prosecuted.—Mr. BURNS sent the following written reply: My honourable friend has asked me to reply to this question.

Communications, Letters, &c., have been received from—

BEAMAN—COOPER.—On Feb. 1st, at St. Barnabas Church, *Addison-road, Kensington*, W., Winfrid Kelsey Beaman, Lieutenant, Royal Army Medical Corps, to Mary Ringland Cooper, of 1, *Kensington Hall-gardens*, W., only daughter of the late Mrs. W. A. Cooper.

DEATHS.

GALTON.—On Feb. 7th, at Chunam, Sylvan-road, Upper Norwood, John Henry Galton, M.D. Lond.

REAN.—On Feb. 6th, at Oxford-gardens, W., Surgeon-General William Henry Rean, M.D., retired, Indian Army, in his 81st year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

which he had discovered in 1880 in his own saliva with the coccus which he had more recently isolated in cases of lobar pneumonia, but fell into the error of supposing it to be identical also with Friedländer's micro-organism. All this confusion and misunderstanding was, however, cleared up by the researches of Fraenkel, who in April (before the Congress für Innere Medicin, Berlin) and July, 1885, independently recognised the identity of Sternberg's coccus of *sputum septicæmia* with the pneumococcus, and quoted three cases of lobar pneumonia from which he had cultivated it on *solid media*. In communications during the course of the following year he published fuller accounts of his observations and gave differential descriptions of the pneumococcus and Friedländer's pneumobacillus.

In May, 1886, Weichselbaum communicated to the Gesellschaft für Aerzte (Vienna) a report to the effect that he had examined the exudate from 129 cases of pulmonary inflammation, of which 94 were undoubted lobar pneumonia and from which he cultivated the pneumococcus. In 21 of the same series he isolated a streptococcus and from nine cases only did he obtain Friedländer's pneumobacillus.

Early observers, as I have previously remarked, adhered rigidly to the postulates of Koch and attempted to prove that the action of the pneumococcus was special and specific and that its pathogenic properties were always, and solely, directed to the production of a special form of pulmonary inflammation which resulted in the consolidation of considerable areas of the lung tissue. When, however, they attempted to reproduce this lesion in laboratory animals it was found that the experimental animals rapidly succumbed to a general septicæmia, unaccompanied by lobar pneumonia, and it was necessary to continue the investigations until a combination of conditions sufficiently comparable to that obtaining in man was discovered, when the experimental infection resulted in the production of lobar pneumonia. This combination of conditions was finally obtained by Gamaleia (1888) working in the Pasteur Institute, for by employing sheep and dogs for his inoculation experiments he was successful in reproducing the typical pathological lesions of acute lobar pneumonia.

During the early inquiries into the life-history of the pneumococcus each worker, almost, applied to the organism a different title. The chief of these were as follows:—

1. Micrococcus Pasteuri	Sternberg.
2. Micrococcus pneumoniæ crouposæ	„
3. Microbe septicémique de salive	Pasteur.
4. Coccus lanceolatus	Talamon.
5. Coccus of sputum septicæmia	Fraenkel.
6. Bacillus septicus sputigenus	Flügge.
7. *Bacillus salivarius septicus*	Biondi.
8. Diplococcus pneumoniæ	Weichselbaum.
9. Diplobacillus pneumoniæ	Fraenkel and Weichselbaum.
10. Pneumococcus	„
11. Pneumonia coccus	„
12. Meningococcus	Foà and Bordoni-*Uffreduzzi.*
13. Micrococcus lanceolatus capsulatus	„
14. Diplococcus lanceolatus capsulatus	„
15. Diplococcus lanceolatus fibrinogenicus ...	„
16. Diplococcus lanceolatus œdematogenicus	„
17. Gleococcus *of* Fraenkel	Klebs.
18. Streptococcus *lanceolatus Pasteuri*	*Gamaleia.*

Of this formidable list only three have obtained any vogue—viz., pneumococcus, diplococcus pneumoniæ, *and* streptococcus lanceolatus. The last-named has the advantage of accurately describing the organism and is the title preferred by the purist. The first possesses the virtue of brevity, is the one in commonest colloquial use, and is the one that will be adhered to throughout the present paper.

So far all the investigations had been directed to the association of the pneumococcus with lobar pneumonia, but now that the causal nature of the association of the organism with this disease had been firmly established clinical observations concerning manifestations of the pathogenetic properties of the pneumococcus other than, but frequently associated with or following, lobar pneumonia gradually accumulated. For instance, Foà and Carbone (1894) encountered lesions in the human subject which, although apparently all due to invasion of the tissues by the pneumococcus, varied so widely in their histological characters that they felt compelled to recognise two distinct varieties or strains of this organism, which they designated respectively "œdematogenetic" and "fibrinogenetic"—descriptive adjuncts which sufficiently indicate the main histological characters of the lesions produced. *The first they named* the meningococcus and the second the pneumococcus.

As the numbers of workers increased, however, and animal experiments were multiplied it was found that—as in the case of other pathogenic bacteria—one and the same strain of pneumococcus could, by varying the conditions of experiments, be induced to produce widely varying lesions, while clinical observations showed the presence of the pneumococcus, obviously in a causal capacity, in very different pathological conditions.

SOME OF THE LESIONS DUE TO PNEUMOCOCCUS INFECTION.

Meningitis.—Foà and Bordoni-Uffreduzzi reported to the Royal Academy of Medicine, Turin, their observations on lanceolate diplococci which they had discovered in the exudation of cases of epidemic cerebro-spinal meningitis. They further identified this organism with Fraenkel's pneumococcus and published a most valuable study of its biological properties and cultural varieties. Many cases of meningitis associated with or following upon pneumonia have since been recorded by Weichselbaum, Netter, and others, and the disease has been frequently reproduced in the laboratory by means of subdural inoculations of the pneumococcus. At the same time, instances of primary infection of the central nervous system by the pneumococcus have accumulated, and when Wolff in 1897 carefully analysed the literature dealing with meningitis he found that the pneumococcus was recorded as the causative factor in over 40 per cent. of the total number of cases. Osler records a series of 93 cases of meningitis, of which over 22 per cent. were due to the pneumococcus. Brodie, Rogers, and Hamilton (1898), too, have described cerebro-spinal meningitis due to the pneumococcus consecutive to an epidemic form of rhinitis in African natives; and Turner, in a still more recent (1907) article notes the presence of 17 cases of *pneumococcic meningitis* (out of a series of 70 which were investigated bacteriologically) in natives employed in the Rand mines.

Ulcerative endocarditis.—Endocarditis usually affecting the aortic valve is frequently due to the pneumococcus. Both the vegetative and ulcerative varieties have been produced experimentally by Kruse, *Pansini*, *Vanni*, Netter, and others who, however, noted that unless some injury of the valve already existed an endocarditis could rarely be set up. The method usually adopted, therefore, was to pass a sterile probe down the carotid artery into the left ventricle and injure the valve, then to inject virulent broth cultures of the pneumococcus either directly into the heart or subcutaneously.

Suppurative pericarditis.—This is practically always consecutive to lobar pneumonia and pleurisy. Sometimes the exudation is sero-pus or serum containing large flakes of fibrin rather than ordinary pus. At other times the heart is enveloped in a thick membranous layer of fibrin-entangled pus cells and the visceral layer of the pericardium lined with a similar exudation, the two surfaces being separated by a perfectly clear serous fluid.

Pleurisy.—An exudation of clear serous fluid into the pleural cavity resulting from the extension of the pneumococcus through the lung to the visceral layer of the pleura is the commonest sequel of pneumonia, and at the same time, as it is usually readily reabsorbed and the pleura rarely requires opening, is the least important. Frequently, however, the pneumococcus multiplies rapidly in this fluid which then has a sero-purulent character and contains numerous large flakes of fibrin or may gradually merge into a fluid having all the appearance of ordinary pus. The pneumococcus, however, is often able to give rise to a serous or sero-purulent pleurisy quite apart from any antecedent of pneumonia, and this observation is of frequent occurrence in experimental inoculations into the trachea of the rabbit (through a catheter passed through the larynx). Under these conditions the pneumococcus may actually enter the lung, pass through the pulmonary tissues without leaving behind it any trace of inflammatory reaction, pass through the pleura, and reaching the pleural cavity produce a marked pleurisy which often extends to the enveloping membrane of the heart and causes a large collection of serous exudation within that sac. The frequency of the pneumococcus as the exciting cause of serous pleurisy is well shown in the following table, which includes those cases investigated bacteriologically in Guy's Hospital during the past five years—24 out of a total of 82, or a percentage of 29, being the result of the analysis.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.

WEDNESDAY.—4 P.M. Lecture:—Dr. Perkins: Cases from the Wards.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Dr. Still: Dyspepsia in Children past the Period of Infancy.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Kensington News, Westminster Gazet West Sussex Gazette, Daily Dispatch (Manchester), Montreal Gr (Canada), Dublin Daily Express, Dublin Evening Telegraph, Advertiser, Liverpool Daily Post and Mercury, Daily Ne Herald, Yorkshire Observer, Broad Arrow, &c.*

being of considerable virulence and in the third of very low virulence.

In order to gain some idea of the frequency with which the pneumococcus is met with in situations other than pulmonary tissue and of the frequency with which its presence provokes the formation of pus, I have examined the records of the bacteriological department of Guy's Hospital for the past five years. Arranged in tabular form, the results conclusively demonstrate the validity of the claim of the pneumococcus to be considered, potentially at any rate, a pyogenic coccus, for after subtracting seven cases of septicæmia, two of infective endocarditis, and 24 of pleurisy with clear fluid, we have no less than 168 instances—rather more than 1 per cent. of the total number of bacteriological specimens for the five-year period—where the presence of the pneumococcus had led to the formation of exudations possessing all the physical attributes of pus.

I have carefully excluded from the above table all cases in which the identity of the pneumococcus isolated from the pus was not completely established by methods above criticism, and in this connexion I would deprecate the diagnosis of "pneumococcic" suppuration by microscopical examination of stained films alone. It is far from rare when inquiring as to the attributes of the strain of pneumococcus implicated to find that the diagnosis rests on the slender foundation of the observation of "diplococci" in the pus, regardless of the fact that the pneumococcus is not by any means the only organism which assumes this morphological character in morbid exudates. The streptococcus very frequently, and the staphylococcus aureus and also staphylococcus albus by no means rarely, assume this type of division under similar conditions. Nor is the term "capsulated" as applied by observers who are satisfied with such cursory examination any more convincing, for often the note that this anatomical peculiarity of the pneumococcus is present will be found to depend solely on the "negative" evidence of an unstained halo—such as is so frequently due to the contraction of rapidly dried serum from the periphery of the paired coccus—around the organism, which halo, be it noted, will probably be found surrounding nearly every particle of dirt on the same slide.

ATTRIBUTES OF THE PNEUMOCOCCUS.

Consequently it will be well to recapitulate briefly now those essential characteristics of the pneumococcus which are deemed necessary by the bacteriologist to establish its identity—although I may at once say I have no intention of entering minutely here into the laboratory habits of this micro-organism. Incidentally it must be mentioned that for convenience of reference the particular pneumococcus isolated from each individual is designated by a name, letter, or number prefixed by the word "race," or better "strain," and when a number of strains are found to possess similar characteristics they are grouped together under the heading of "Type."

Characteristics of the Pneumococcus.

Technically described the pneumococcus is an aerobic, facultative anaerobic, non-motile, highly parasitic coccus occurring in body fluids as pairs, of which the individual members are lanceolate or "candle-flame" shaped, with the rounded bases in apposition, and surrounded by a mucinous capsule which can be positively demonstrated by MacConkey's, Muir's, or one of Hiss's staining methods; or as short chains, also capsulated; occurring in artificial cultivations as more nearly spherical bodies in pairs or short or long chains; staining with the ordinary aniline dyes and not decolourised by Gram's method; growing upon artificial nutrient media at the temperature of the body only, but not upon gelatin at 20° C. (Certain saprophytic forms devoid of virulence, or practically so, are capable of multiplication at temperatures approximating to what is spoken of as room temperature—i.e., 20° to 22° C.—but with these races we are not at present concerned.) Multiplying in broth of reaction varying from + 12 to + 6 with the production of a uniform turbidity; in litmus milk with the production of an acid reaction, occasionally accompanied by clotting; upon agar and inspissated serum as translucent discrete circular, hemispherical or slightly flattened colonies; upon agar over the surface of which sterile rabbits' or human blood has been smeared, in similar manner but more freely than upon ordinary agar, and accompanied by a discolouration of the blood due to the transformation of the oxyhæmoglobin to methæmoglobin, which is an almost pathognomonic feature of the growth of this coccus; and in the serum of animals that have been immunised to the pneumococcus in the form of a flocculent deposit in an otherwise clear fluid, the flocculi being composed of felted masses of long and convoluted chains of pneumococci.

Finally, and most important of all, is the fact that a pneumococcus isolated *from a definite lesion* in the human subject is markedly pathogenic for the rabbit. Speaking generally, if injected into the peritoneal cavity of this animal it will produce an acute septicæmia and cause the death of the animal in one, two, three, or four days, while the organism can be recovered from the blood of the general circulation and from all the organs in a state of purity. The dose usually employed for this purpose is the entire growth from the surface of one 24-hours-old blood agar tube cultivation emulsified in one cubic centimetre of broth. Usually a dose many thousand times smaller than this suffices, but I have never yet found it necessary to employ a larger one.

Interesting but of minor importance from the point of view of identity is the power possessed by the pneumococcus of splitting up certain carbohydrate substances when these are dissolved in the medium in which the organism is growing. The substances generally used in these tests are dextrose, lævulose, galactose, lactose, saccharose, maltose, mannite, dextrin, and inulin. The first six of these are always acted upon by the pneumococcus, and if the medium, originally neutral in reaction, is tinted with litmus solution, the activity of the pneumococcus is indicated by the change in colour associated with the presence of an acid reaction. The remaining three compounds are sometimes but not invariably "fermented" by the organism under discussion, hence the contention of some American observers that the fermentation of inulin by the pneumococcus is so constant a character as to be of the highest value in diagnosis is not borne out in every-day work.

Having indicated the general characters of the cocci isolated from the varied *materies morbi* already tabulated the question that next arises is how to explain the varying pathogenetic properties exhibited by the pneumococcus. Before referring to the experimental work which has been

Erasmus Wilson Lecture

ON

THE PYOGENETIC ACTIVITIES OF THE PNEUMOCOCCUS.

Delivered before the Royal College of Surgeons of England on Feb. 12th, 1908,

BY J. W. H. EYRE, M.D., M.S. DURH., M.R.C.S. ENG., D.P.H. CAMB.,

BACTERIOLOGIST TO GUY'S HOSPITAL AND TO ST. MARY'S CHILDREN'S HOSPITAL, PLAISTOW; LECTURER ON BACTERIOLOGY AT THE MEDICAL AND DENTAL SCHOOLS OF GUY'S HOSPITAL.

INTRODUCTION.

GENTLEMEN,—In 1881 Ogston of Aberdeen published an account of his observations upon the microscopical constituents of surgical pus which enabled him to state that minute spherical bodies, "micrococci," were usually present in this pathological product of infected wounds. Moreover, he differentiated these cocci into those occurring in irregular masses—"grouped micrococci"—which were usually associated with circumscribed abscess formation, and those which occurred in rows like strings of beads—"chain micrococci"—which were usually found in connexion with the spreading "cellulitis" type of suppuration. Three years later Rosenbach published the results of his investigations which fully confirmed the earlier observations of Ogston. This second worker succeeded in isolating staphylococci and streptococci, as they were now termed, cultivated them upon artificial media in the laboratory, and differentiated some of the several varieties included in this first general morphological classification. For the next decade, no matter in what situation or association it presented itself, pus was pretty generally regarded as the outcome of infection by members of the staphylococcus and streptococcus "pyogenes" groups—a result largely due to a too literal interpretation of Koch's dicta, which laid it down that in order to establish a claim for the specificity of any newly discovered bacterium, that organism must be shown to be constantly present in some particular and definite lesion; must be capable of isolation and cultivation outside the animal body; and on its reintroduction into a suitable host must *reproduce the original lesion*. Hence as the specific etiological factors of the various bacterial infections were recognised and isolated attention was invariably first directed to the reproduction of the original lesions in their entirety, and subsidiary phenomena such as the provocation of pus formation were entirely disregarded, or, again instancing the formation of pus, regarded merely as the result of accidental and preventable contamination with the so-called "pyogenic" cocci already referred to. And it is only within recent years, since, in fact, the inter-reactions of *seed and soil*, of *bacterial irritant and tissue cell*, have been the subjects of extended study that the principle has been generally recognised that practically any and every pathogenic bacterium possesses the power, under some certain combination of factors, of initiating purely pyogenic processes in place of, or in addition to, its particular specific lesion.

Perhaps the most striking illustration of the above statements that can be adduced is afforded by a study of that organism which forms the subject for our present consideration. First studied in its association with one form of inflammatory reaction in pulmonary tissue—viz., acute croupous or lobar pneumonia—its specificity in this connexion was conclusively established before its potentialities in other directions received any but the scantiest consideration. Indeed, it is not so many years ago that the definite statement was made—in all sincerity and as representing the established conviction of a large body of observers—that the pneumococcus was of itself never responsible for the formation of pus, and despite the fact that the presence of the pneumococcus could so readily be demonstrated in those purulent collections within the pleural cavity that are frequently associated with pneumonia, such empyemata were invariably regarded as the direct result of secondary infection with some one or more of the ordinary pyogenic staphylococci or streptococci. The pyogenetic activities of the pneumococcus itself have, however, now been demonstrated experimentally in so complete a manner that the present seems a fitting opportunity to review our knowledge of the subject upon which present-day opinions are based.

HISTORICAL SUMMARY.

The micro-organism I have chosen for the subject of my lecture was first discovered by Sternberg in September, 1880, in the course of some investigations on malarial fever. By means of inoculation experiments he found that his own saliva was pathogenic for rabbits and he isolated a definite diplococcus, which he considered the cause of such pathogenicity, and to it gave the name "micrococcus Pasteuri." This he described in a report to the National Board of Health (U.S.A.), which, however, was not then published but to which he refers in the National Board of Health Bulletin of April, 1881.

In January, 1881, during a discussion following the reading of a paper ("Recherches Expérimentales sur la Transmission du Virus Rabique de l'Homme au Lapin," par MM. Raynaud et Lannelogue, Jan. 18th, 1881) before the Paris Academy of Medicine, Pasteur stated that in December, 1880, he inoculated two rabbits with saliva from a fatal case of hydrophobia, that of a boy, four hours after death. The rabbits died in 36 hours and a new bacterium was discovered in their blood shaped like the figure 8 and surrounded by a gelatinous capsule. It was virulent in broth cultures where it often formed chains. He expressed his ignorance of its relation to rabies but distinguished between the new organism and his "vibrion septique"—i.e., the bacillus of malignant œdema. For the next few months communications were made to the Academy in rapid succession confirming these observations, and a commission was appointed to investigate the subject. Pasteur reported to this commission in April, 1881, that he had found the new organism in the saliva of one more fatal case of rabies and three fatal cases of broncho-pneumonia, and had failed to find it in the saliva of three persons dead from other diseases.

Vulpian (1881) stated that he had found the micro-organism in a virulent condition in the saliva of healthy individuals.

In 1881 also Ebert and Koch and in the following year Friedländer, Leyden, and Günther demonstrated microscopically the constant presence of a diplococcus in the lungs in cases of lobar pneumonia. The two latter, moreover, described the surrounding capsule as being present in specimens made from the fluid drawn from the hepatised lung itself during life by means of a sterile syringe, but they were unsuccessful in obtaining pure cultures of the organism.

In 1883 Matray and Ziehl studied cases of pneumonia and fully confirmed these observations.

In the meantime, and on the experimental side Griffini and Cambray inoculated rabbits with pneumonic sputum and regularly produced a fatal septicæmia; continuing their experiments they were equally successful in reproducing the septicæmia in other rabbits by using for the purpose of inoculation blood taken from the original rabbits after death.

In November, 1883, Friedländer described cultures upon solid media of what he considered to be the pneumococcus. He stated that his organism was an oval coccus, surrounded by a gelatinous capsule, which readily grew on gelatin at the ordinary room temperature. These observations gave a great impetus to the bacteriological study of croupous pneumonia by the modern methods, although we are now aware that Friedländer's "oval coccus" was in truth a bacillus and in no way concerned in the causation of the disease.

Two months later (1884) before the Société Anatomique Talamon described cultivations in bouillon of the genuine diplococcus and showed cultures grown at the body temperature from pneumonic exudates. Two of these cultivations were absolutely pure. Of 20 rabbits inoculated into the chest cavity with these cultures 16 died from septicæmia, often accompanied by fibrinous pleurisy and pericarditis, and sometimes by a true lobar pneumonia. The blood and exudates of these fatal cases always contained cocci, and yielded pure cultures capable of producing similar inoculation results. Guinea-pigs and dogs, he stated, were immune. He had also found the coccus in fluid drawn during life from the hepatised lung—in man—in eight cases. In one fatal case it occurred in the general circulation at the moment of death.

As Friedländer and Talamon were working with two distinct organisms a good deal of confusion resulted from their conflicting statements. As an example of this Sternberg in April, 1885, read a paper before the Pathological Society of Philadelphia, pointing out the identity of the coccus

TABLE V.—*Initial Virulence of Various Strains of Pneumococci.*

dose was either 0·000001 or 0·0000001 of a loopful, and control plate cultivations made with that quantity of the emulsion corresponding to 0·000001 showed that sometimes it contained 200 cocci, sometimes 20. If it contained 200 cocci the minimal lethal dose was 0·0000001 of a loop; if it only contained 20 the animal that received 0·0000001 of a loop was usually unaffected, and 0·000001 of a loop proved to be the minimal fatal dose.

Now in the experiments already quoted the introduction of the pneumococcus into the subcutaneous tissues of an animal of but feeble resisting power—i.e., the young rabbit—was followed by acute and rapidly fatal septicæmia, while the same organism similarly used to infect an animal of greater resistance—i.e., the full-grown rabbit—led to the formation of a localised collection of pus. Conversely, it seemed possible that septicæmia in the adult—I purposely specify the adult in order to avoid touching upon the question of greater susceptibility in the infant and the aged—would be the result of infection by a pneumococcus of extremely high virulence, while pus formation would be due to the inroads of attenuated pneumococci. Sometimes this does obtain. For instance, a recent case of primary peritonitis yielded a pure culture of a pneumococcus the virulence of which was so low that two loopfuls of the optimum cultivation were required to produce fatal infection in the rabbit, whilst a morphologically identical pneumococcus from a fatal case of septicæmia was of standard virulence—that is to say, was two million times as powerful. Now, supposing it were possible to apply the results of these observations without reservation to pneumococcic infections in man, it should be a simple matter, given the nature of the lesion produced, to forecast the approximate virulence of the strain of coccus isolated; or, given the virulence of the organism, to predict the characters of the lesion that would follow its introduction into human tissues. Thus the pneumococcus of high virulence should produce septicæmia and the pneumococcus of low virulence should induce the formation of pus. But, on the other hand, two strains of pneumococci of equal and standard virulence were isolated from two cases which differed widely in the clinical manifestations, the one being a chronic otitis media, the other being a fatal case of pneumonia, suppurative pericarditis, and suppurative cerebrospinal meningitis. However, the hypothesis I have suggested was put to the test and a large number of strains isolated and the virulence of each estimated, with the result that it proved untenable, for the simple reason that no constant relationship could be shown to exist between any given pathological manifestation of pneumococcic activity and either high, low, or medium virulence. The general results obtained will be readily appreciated from the accompanying details which are arranged in tabular form.

SIZE OF DOSE.

The next point to which my attention was directed was the relationship, if any, that existed between the size of the dose of infective material—or if you prefer it the number of pneumococci injected—and the character of the resulting lesion. Under certain conditions it was found that the size of the dose exercises a direct bearing upon the subsequent lesion—a result which was arrived at in a manner illustrated by the following example. In this experiment full-grown male rabbits were injected with cocci from one and the same

TABLE VI.—*Minimal Lethal Dose 0·000001 loop. Virulence Attenuated by Four Successive Subcultivations upon Ordinary Agar. (Pneumococcus Strain "Hunt.")*

Rabbit.	Sex.	Weight in grammes.	Dose of pneumococcus.	Method of infection.	Lesion.	Result.
No. 31	M.	1230	0·0000001	Subcutaneously.	Transient local œdema.	Unaffected.

Empyema.—Pus due to the activities of the pneumococcus is perhaps most familiar to the surgeon in the shape of empyemata. An analysis of the cases of empyema in Guy's Hospital investigated bacteriologically during the past five years shows that 77 per cent. are due to this organism alone.

The naked-eye characters of the purulent fluid are sometimes practically diagnostic. While the pus from cases of pneumococcic empyema or pneumococcic peritonitis may present the greenish yellow colour and creamy consistence of what used to be called laudable pus, it is more often a yellowish fluid of somewhat thinner consistence, which, although quite homogeneous when removed from the body, if collected in a test tube and allowed to stand soon undergoes auto-sedimentation and separates into two layers of about equal bulk, the lower yellow layer consisting of pus cells and the upper a translucent, opalescent fluid quite clear except, perhaps, for the presence of a few flakes of fibrin. The microscopical examination of the fluid is often very characteristic, showing in addition to the pneumococcus itself many involution forms, empty capsules, dead cocci, and deeply staining particles. The contention of the clinician that a pneumococcic empyema is always primarily purulent and that the serous pleurisy due to this organism never becomes purulent obtains very little support either from direct observation or from inoculation experiment. If in a series of intrapleural or intraperitoneal inoculations of the rabbit the conditions are so arranged that the experimental animals shall die at varying periods it will be found at the post-mortem inspection that where death has rapidly followed on the injection the exudation is clear serum teeming with pneumococci. If death is delayed to three, four, five, or more days every gradation in the character of the exudation, from clear serum, sero-pus to creamy pus, will be met with. In the same way the gradual change in the character of the fluid can be noted clinically in many cases if exploration of the chest is repeated from day to day.

Otitis media.—The pneumococcus has been frequently isolated from, and in many cases found in pure culture in, the pus of otitis media. Zaufal (1888), who recorded many cases, was able to produce this disease experimentally by means of inoculations into the tympanic cavity.

Arthritis.—The pneumococcus has also been isolated from the serous or purulent exudation in mono- and poly-arthritis occurring either as a primary manifestation of pneumococcic septicæmia or during the course of a lobar pneumonia, the earliest cases being those described by Vogelius (1897). The sterno-clavicular joint, shoulder, hip, and knee are those most commonly affected. Gabbi produced arthritis experimentally by injuring joints, either by traumatism or the use of chemical irritants, and then inoculating virulent cultures of the pneumococcus subcutaneously.

Pneumococcic peritonitis.—Peritonitis due to the pneumococcus differs in character according to whether it occurs in adults or in children. In the former it is usually diffuse and observations are now accumulating which show that the appendix is not an uncommon point of departure. In children, on the other hand, the peritonitis is very frequently local in its distribution, being early shut off from the general cavity by fibrinous adhesions. Pneumococcic peritonitis was first noted (1880) by Sevestre. Dieulafoy collected a number of cases; and Bryant (1901) contributed a further series. Marchaux (1899) recorded vaginitis and peritonitis as common complications of pneumonia amongst natives in Africa.

Localised abscess formation.—Circumscribed collections of pus, subcutaneous, intramuscular or within some viscus, have often been described (e.g., Batten and Foulerton, 1901), and can readily be produced experimentally in laboratory animals.

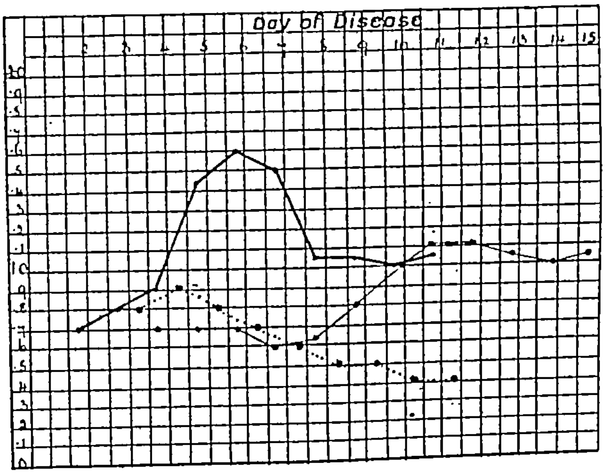
Conjunctivitis, &c.—On the continent the pneumococcus is said to infect frequently the conjunctival sac, producing an acute conjunctivitis—often in epidemic form—but is not so commonly found in this situation in England. Gasparini has also recorded the pneumococcus as giving rise to keratohypopion.

Varia.—Finally, the pneumococcus has been recorded as causing, among other lesions, epiphysitis, osteomyelitis, periostitis and necrosis, thyreoiditis, parotitis, tonsillitis, follicular and membranous, gastritis, nephritis and perinephritis, endocervitis, &c.

Enough has been said to show the protean character of the lesions for which the pneumococcus has been recorded as the responsible cause. In order to explain the presence of the pneumococcus in the widely separated situations indicated by the foregoing summary it is necessary to consider for a moment how the organism gains access to the body tissues in the first instance. I have already mentioned that the pneumococcus was first discovered as the result of the examination of the saliva of a healthy individual. Sternberg records the organism as present in the same situation in 20 per cent. of the healthy persons examined; Netter in 15 per cent.; Washbourn and myself, in a limited number of individuals (20), in 30 per cent.; in a more extended series I have found it present in 16 per cent. It is also commonly found in the normal nose, its presence being recorded by Netter, Kurth and von Besser, and others—its percentage incidence being nearly 30 and the tonsillar crypts frequently harbour the coccus. In many instances the pneumococci isolated from these situations are of low virulence; indeed, sometimes they are avirulent, and at other times of a high degree of virulence. Washbourn and I carefully studied a number of them and found that even if the original virulence was low it could readily be exalted. A few varieties, however, were only exalted in virulence with great difficulty and then soon returned to their original condition. Hence the portal of entry is in the vast majority the respiratory tract and the cells of the upper air passages form the first line of defence. The pulmonary tissues constitute the second line of defence. Once arrived at the lung alveoli the pneumococcus readily enters the blood capillaries and so reaches the general circulation. In this situation if antibodies in sufficient quantity are available the invader is destroyed; short of this the cocci become deposited in areas of lowered bacterioscopic pressure and so give rise to localised infections, or multiplying in the blood stream produce a general septicæmia. Thus pneumonia may be regarded as a defensive process designed to prevent metastases or septicæmia. At its best, however, it is not absolutely efficient. Banti, Prochaska, and others maintain that pneumococci are invariably present in the blood in pneumonia and although years ago both Washbourn and myself were of opinion that the cocci only arrived at the peripheral circulation immediately prior to the fatal termination improved methods for the examination of the blood for the presence of micro-organisms lead me to believe that the cocci are present during the first two or three days of the disease even in the least severe cases of pneumonia. Next to the respiratory system the alimentary tract is probably the most common channel of entrance. Foulerton's case of gastritis and the numerous recorded cases of pneumococcic appendicitis place this method of infection beyond doubt. It is therefore easy to see how any organ or tissue may become the seat of pneumococcic infection. Finally, as affording a possible explanation of pneumococcic peritonitis occurring more commonly in the female than the male, Doyen records the presence of non-virulent pneumococci in the healthy vagina and cervix, and I have isolated the coccus from these situations in three instances—in two the organism

Macdonald, who very carefully studied the clinical aspects of pneumonia with reference to the formation of pneumococcic opsonin throughout the course of the disease, published his results in 1906 and showed that the movements of the curve representing the opsonin index afforded an exact record of the measure of resistance opposed by the patient to the inroads of the organism. My own observations fully confirm Macdonald's, and, moreover, show that the resistance of the individual so far as can be measured by his opsonin response to any given pneumococcus infection conforms to one of three main classes which are represented by the three accompanying curves. Two of these opsonin curves are compiled from estimations carried out in connexion with that clinical form of lobar pneumonia in which crisis takes place and that which recovers by lysis in order to contrast them with the curve obtained in the acute septicæmia which terminates in death; and although we are not immediately concerned with pneumococcus infection of the lung tissue I make no excuse for presenting them here, as being derived from acute cases they illustrate my point much more concisely than would be the case if they had been derived from chronic suppurations.

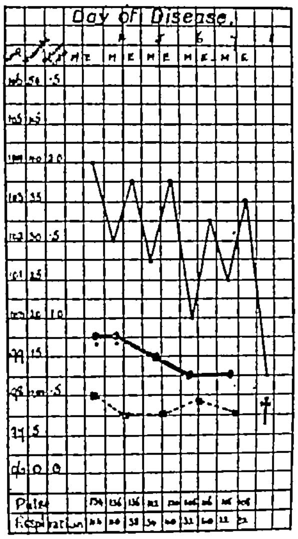
CHART 1.—*The Opsonin Index in Pneumococcic Infections; Three Leading Types.*



In the third, represented by the lowermost (continuous) curve, the process by which opsonins are elaborated is completely paralysed, as the result possibly of an extremely heavy dose of infective material, or of infection by an extremely virulent pneumococcus, or of infection directly into the blood stream, or more probably of a combination of all of these factors. In the second (dotted line), the production of pneumococcus opsonin is temporarily suspended, perhaps owing to the existence of, say, any two of the factors just enumerated, but after a time recovery of tone takes place, production goes on in excess of expenditure, and finally sufficient opsonin is produced and thrown out into the circulation to subdue the invader. Incidentally it may be mentioned that this type of case is most frequently the one in which the pneumonia is associated with suppurative lesion. In the first (thick continuous line) the immunising machinery promptly responds to the call made upon it, at once elaborates opsonin in excess, with the result that the pneumococcus is rapidly destroyed and recovery takes place. [Occasionally, be it noted, this type of curve after returning to the normal suffers a further fall, and some few pneumococci remaining in some far distant spot, in an almost moribund condition, take on a fresh lease of life and some small localised suppuration results. In such circumstances the opsonin curve would be expressed by tacking the beginning of the second curve in the chart on to the end of the first.] In other words, in the third instance the immunising machinery is badly overstrained, in the second understrained, and in the first severely but not unduly strained.

As suggesting a possible source of the pneumococcus opsonin I have inserted in the two following charts (Charts 2 and 3) the leucocyte curve as well as the opsonin curve. In the fatal case leucocytosis is absent, the opsonin index falls gradually and continuously. In the second case the fall in the opsonin index that is practically always noted in the early stages of an acute infection is associated with a considerable leucocytosis which becomes less marked as the amount of available opsonin increases.

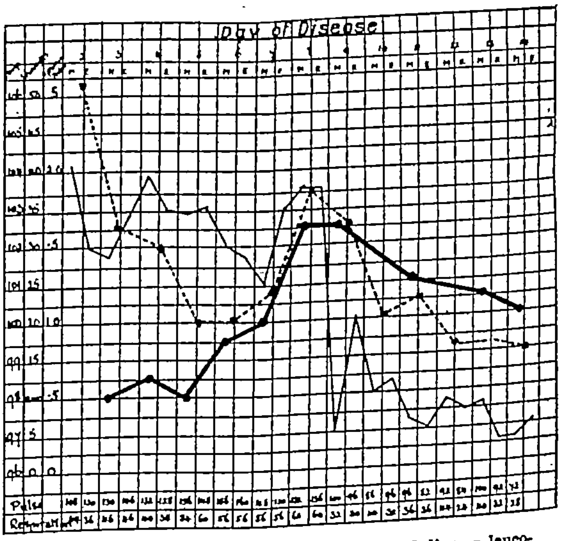
CHART 2.—*Fatal Case of Pneumococcic Septicæmia.*



Upper thin line = temperature; middle thick line = opsonic index; lower dotted line = leucocytes per cubic millimetre of blood.

I cannot conclude without a few remarks upon what may be termed the bacteriological therapy of pneumococcic infections. Many of the earliest students of the life-history of the pneumococcus—the Klemperer brothers, Foà and Carbone, and in this country Washbourn—showed that the blood serum of immunised animals protected other animals from the effects of pneumococcus inoculations if injected simultaneously or even subsequently. Washbourn early in 1897 immunised the horse and about the same time Pane immunised the donkey and the goat with a view to obtaining a potent serum for the treatment of cases in man. Such serum has never been really extensively tested in this country and therefore no very definite opinion can be expressed as to its value. What little evidence there is available is certainly in its favour; for instance, in a small series of six cases of pneumonia collected by Washbourn the serum in three cases exerted a powerful and beneficial effect

CHART 3.—*Case of Pneumonia terminating by Crisis.*



Thin continuous line = temperature; dotted line = leucocytes; thick continuous line = opsonic index.

carried out in the attempts to answer satisfactorily this question I would remind you of the essential factors that are concerned in this question of infection, or of immunity if you prefer to regard it from the standpoint of the defenders rather than that of the invaders. Briefly, those factors which we shall now deal with here are: (1) the type of the organism; (2) the virulence of the organism; (3) the numbers of the infecting organism; and (4) the defensive powers of the invaded tissues, e.g., the resistance or the susceptibility of the animal cell or of the invaded individual.

Types of Coccus.

During some of our observations upon the natural history of the pneumococcus Washbourn and I noted that although all strains of virulent pneumococci produced a rapidly fatal septicæmia when introduced into the peritoneal cavity of the rabbit, yet if the injection was made into the subcutaneous tissue the various strains frequently presented striking differences in the histological characters of the local lesions they produced. Thus in the case of strains recovered from the hepatised lung in cases of pneumonia, fibrinous exudation formed the bulk of the material at the site of inoculation; while when strains isolated from broncho-pneumonia and from suppurative lesions were injected the local reaction consisted mainly of accumulations of polymorphonuclear leucocytes. These two types of cocci which we referred to as the "fibrinous" and the "cellular" types respectively agreed in some measure with those previously described by Foà and the hope was raised that the existence of two distinct and fixed varieties of pneumococci would afford an explanation of the differing clinical phenomena provoked by the invasion of human tissues by this organism in general, and in particular of the occurrence of acute septicæmia on the one hand and of pus formation on the other. Such, however, was not the case, for it was soon found when the experiments were carried further that by varying the conditions of the experiment either type was capable of giving rise to pus formation or to septicæmia. As an example of the different results obtained by varying one factor of the experiment—viz., the resistance of the tissue cell—I may instance the infection of the subcutaneous tissue of the abdomen of the rabbit.

(*a*) If we select for the experiment a young rabbit we find that a small dose of either of these types of the pneumococcus will cause death within 48 hours from acute pneumococcic septicæmia. At the seat of inoculation the reaction, usually small in amount and limited in area, is practically always œdematous in character, and either of the serous, sero-hæmorrhagic, or more rarely the hæmorrhagic type.

(*b*) If, however, we substitute a half-grown rabbit and inject a similar dose of the same cultivation the animal survives for a much longer period, say three or four days, or even a week. Now the local reaction at the seat of infection is a much more extensive process and clearly indicates by both its macroscopical and microscopical characters the particular "type" of pneumococcus that has been employed to produce the infection. It may be either a firm gelatinous exudation consisting of fibrin and leucocytes, together with red blood discs, thrown out and occupying the subcutaneous cellular tissue for a considerable distance around the needle puncture, frequently, indeed, extending down to the peritoneum below; or else a dense, opaque, yellowish exudation consisting almost entirely of small round cells, fibrin being almost entirely absent.

(*c*) Finally, if a fully grown animal is infected with a similar dose of either type the local lesion at the seat of inoculation consists of a larger or smaller circumscribed œdema, usually noticed within 24 hours of infection, which enlarges slightly during the next few days, though remaining strictly localised, becomes soft, and in about ten days contains pus and can be made to fluctuate. If untreated the skin over the abscess undergoes necrosis, sloughs, and gives exit to a thick creamy yellowish pus literally teeming with pneumococci and the animal dies from exhaustion in a fortnight or so, or in some few instances completely recovers.

Again by varying the site of inoculation and introducing the organism either into the peritoneal cavity or directly into the general circulation each type of pneumococcus would produce an acute septicæmic infection irrespectively of the age of the experimental rabbits.

From the clinical aspect exceptions were numerous and it was found that the fibrinous type of pneumococcus was as often isolated from purulent collections unassociated with pneumonitis as the cellular type.

DEGREES OF VIRULENCE.

Then, too, in our early observations Washbourn and myself found that pneumococci isolated from pathological processes in man invariably possessed a certain amount of virulence for the rabbit and so constituted the virulent type of pneumococcus; on the other hand, some strains of pneumococci isolated from various situations in the healthy body were devoid of virulence for that rodent and constituted the avirulent type; whilst between these two extremes every grade of virulence could be recognised. Here again an obvious explanation for the various lesions produced in man as the result of infection by the pneumococcus seemed to be forthcoming and it was at once put to the test. Strains of pneumococci were isolated from various situations and from exudates of very different naked-eye characters and their virulence was tested. The usual rough-and-ready method of estimating virulence by observing the amount of a 24-hours-old broth culture of the organism under investigation needed to produce any given result did not appeal to us, as among other peculiarities of the highly parasitic pneumococcus it does not usually grow well in this medium and when it does it varies from time to time in its rate of growth and moreover rapidly loses its virulence. Cultivations upon blood agar which had previously been described by Washbourn and myself as particularly adapted for the purpose of maintaining the virulence were therefore employed and a more accurate method of estimating the size of the doses, in which a specially manufactured and calibrated loop was always used to remove the growth from the medium was devised. Briefly our method was as follows. One loopful of the 24-hours-old growth at 37° C. was taken from the surface of the blood-agar and thoroughly emulsified in a known quantity (10 cubic centimetres) of sterile broth or saline solution, in a suitable vessel. It was then easy to prepare dilutions, in tenths, of the original loopful by measuring the requisite fractions of this emulsion in sterile graduated pipettes, transferring them to other vessels and adding more saline solution to any desired volume. Thus a series of rabbits could be inoculated with decreasing amounts of the pneumococcus cultivation and the minimal lethal dose ascertained.

The accompanying table shows such a series of inoculations of a strain known as strain "Sudbury," which was originally isolated from the rusty sputum of a case of lobar pneumonia.

TABLE IV.—*Determination of the Minimal Lethal Dose of the Pneumococcus* (*Strain "Sudbury"*).

Rabbit.	Dose of culture.	Method of injection.	Result.
No. 1	1 loopful.	Intraperitoneally.	Death in 18 hours.
" 2	0·1 "	"	" 24 "
" 3	0·01 "	"	" 48 "
" 4	0·001 "	"	" 3 days.
" 5	0·0001 "	"	" 3 "
" 6	0·00001 "	"	" 7 "
" 7	0·000001 "	"	" 7 "
" 8	0·0000001 "	"	Unaffected.
" 9	0·00000001 "	"	"

It was soon found that the different strains of pneumococci differed markedly in their virulence. Of some when first isolated it was necessary to inject an entire blood agar culture to kill the animal. Others, again, were fatal in doses corresponding to one-millionth part of a loop. Usually it was found that even those of comparatively slight virulence would after one or two passages through animals be so enhanced in virulence that the very minute dose just mentioned—the one-millionth part of a loop—now proved to be the minimal lethal dose. Consequently such a degree of virulence came to be regarded as the standard, and a pneumococcus which was fatal in doses of 0·000001 of a loop was spoken of as possessing "standard virulence."

The method already described for estimating the virulence of any given strain of pneumococcus not only enables the bulk of the dose to be measured in terms of a loop with some degree of accuracy but also gives a fairly close approximation to the actual number of cocci contained in at least the smaller doses. For example, working with a pneumococcus of standard virulence it was found that the minimal lethal

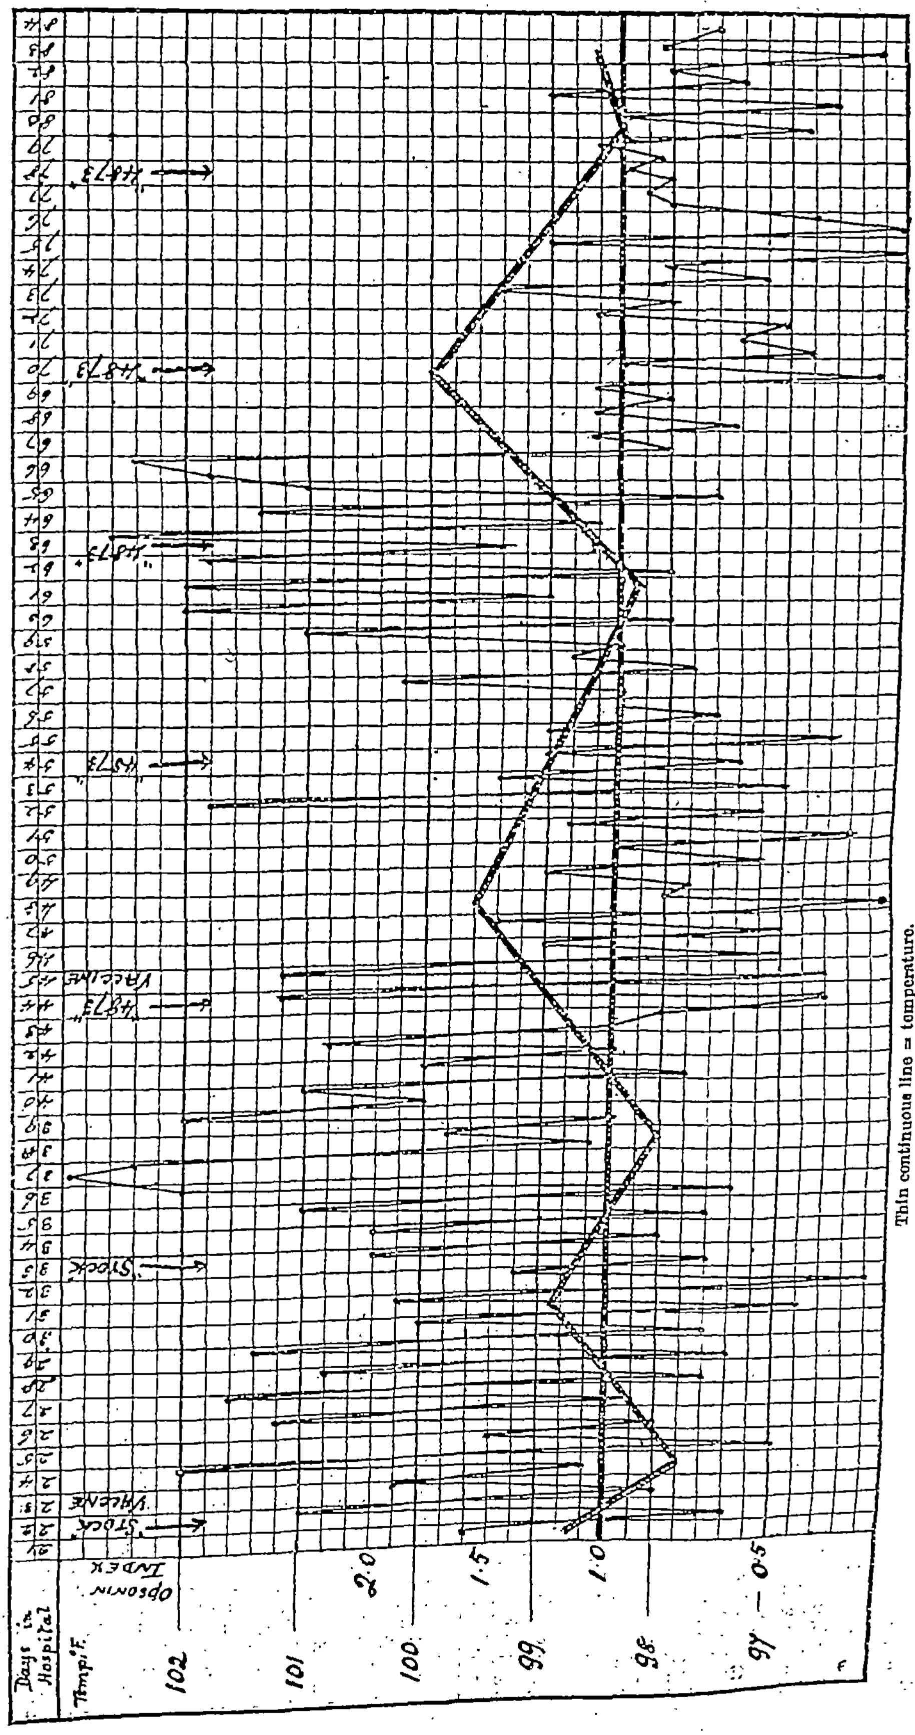


CHART 5.—CASE OF SECONDARY PNEUMOCOCCIC INFECTION OF A TUBERCULOUS PERITONEUM, SHOWING THE EFFECT OF "STOCK" AND "SPECIAL" PNEUMOCOCCUS VACCINES UPON THE OPSONIN INDEX AND UPON THE TEMPERATURE.

cultivation of a strain of pneumococcus (which had been isolated from the lung juice of a fatal case of lobar pneumonia). The factor that was wittingly varied was the size of the dose. The first rabbit received approximately 20 cocci, the next 200, the next 200,000, and the last 200,000,000.

CELL RESISTANCE.

Having investigated the various phases of pneumococcic infection with reference to (1) the biological type and (2) the virulence of the organism concerned, and, incidentally (3), the magnitude of the infective dose without obtaining any satisfactory explanation of the disease lesions produced in man by the invasion of his tissues by the one morphological entity, the pneumococcus, it still remains to inquire into the possibility of the resistance of the cell being the most important factor, and I may say at once that in this direction undoubtedly lies the solution we are seeking. Experimental work had already pointed to the importance of this factor. Indeed, most of the instances which I have already adduced in illustration of the action of the other factors in the problem have also demonstrated to a greater or less degree the influence of this the most important factor. Thus we have seen how the pneumococcus which in the young and immature rabbit is able to produce a rapidly fatal septicæmia, in the adult and fully formed rabbit remains localised to the seat of inoculation, and is at most only able to give rise to a circumscribed collection of pus.

The rabbit forms the subject of the bulk of the pneumococcus experiments, because it is certainly the most susceptible of all the laboratory animals to infection by this organism. The young rabbit is infected with the greatest ease, half-grown animals are slightly more resistant, and fully grown and mature ones are more resistant still, but even in the normal adult rabbit the resistance offered to the pneumococcus is very slight, and that resistance varies to no appreciable degree in different individuals. Now in the process of immunisation the method that gives the most satisfactory results is the preliminary intravenous injection on two or three suitable occasions of "killed" broth cultivations of the pneumococcus. This proceeding is found to confer a certain slight degree of immunity upon the animal, which now survives the introduction of several times the minimal lethal dose of *living* cocci into its subcutaneous tissues, but, and this is the point I wish to emphasise, a small circumscribed abscess almost invariably forms at the seat of inoculation. If this is untreated it bursts, discharges its pus, and then the cavity closes by granulating up. When completely healed the animal is found to be highly resistant to subsequent injections of living cocci.

Many experiments were undertaken in the attempt to devise some means of measuring the resistance offered by the living cell to the onslaughts of the pneumococcus, and in the course of these advantage was taken of the fact already referred to that the pneumococcus when grown in *immune serum*—that is to say, the serum of an immune animal—became agglomerated into masses of convoluted chains which formed flocculi in an otherwise clear fluid, in short because agglutinated. In the course of these observations the serum from the healthy individual of several varieties of mammals was examined as well as that of highly immunised animals of various species, and also serum from subjects suffering or convalescent from natural or experimental pneumococcic infections, and, speaking generally, the constancy of the phenomenon was established. Many other observers, particularly Issalf and Arkharow, also noted the peculiar features of growth in immune sera; indeed, Bezançon and Griffon endeavoured to utilise the agglutinins present in the blood of infected individuals as a method of diagnosis. Pneumococcus agglutinins, however, are only formed in small quantities and for a limited period, and rapidly disappear from the serum, so that it is difficult not only to measure their amount but also, in many instances, to demonstrate their existence, so that for clinical purposes the agglutination reaction in pneumococcic infections has but a very restricted application.

Next the bactericidal action of normal and of immune serum was carefully investigated, and while the observations of Baring and Nissen and Kruse and Pansini relating to the absence of bactericidal substances from the serum of the normal rabbit were fully confirmed it was further found that the serum of immunised animals varied considerably in this respect in that sometimes bactericidal substances were present in considerable amount, although on the other hand they were frequently absent or present only in amounts too minute to be appreciated. Mennes, however, pursuing this line of investigation, found that while the serum of an immunised animal frequently failed to exercise any definite bactericidal action by itself, if white blood cells from either a normal or an immunised animal were added to the mixture of cocci and immune serum the serum so acted upon the cocci as to render them sensitive to the action of the leucocytes, and many of the pneumococci in the mixture were englobed and destroyed by the white cells. This property he stated was peculiar to immune serum.

Then came the epoch-marking and now widely accepted researches of Wright and Douglas, which followed on Leishman's work on phagocytosis, in the course of which the presence of certain bodies designated "opsonins" was demonstrated in human serum—substances which enabled the serum containing them to behave in a manner similar to that described by Mennes in connexion with his pneumococcus immune serum. These observers next devised a very ingenious method for measuring the amount of opsonin in a given serum, by means of which they were able to show that as compared with normal serum, the serum obtained from a recently infected individual or animal contained a diminished amount of an opsonin special and specific for the infecting bacterium. The serum of an immune animal on contrary contained as much as or more of that specific opsonin than the serum of the normal. Finally, by injecting small doses of "killed" cultivations of the bacterium into the subcutaneous tissues of the patient they were able so to stimulate the immunising machinery in the direction of the over-production of specific opsonin as beneficially to influence the course of the infection. Such in bald outline are the experimental data around which Wright and his pupils have built up a complete and extensive system of pathology, diagnosis, and vaccine-therapy. It now remains to indicate its application to pneumococcic infections in particular.

In the first place man, as compared to the adult rabbit, exhibits a very marked resistance to invasion by the pneumococcus, although this resistance varies considerably in different individuals and at different ages. These differences are, no doubt, due to many factors, of which hereditary selection may be one. Another which possibly has a bearing upon this aspect of the question is the situation of the pneumococcus in nature. Some 10 per cent. at least of the healthy population cultivate the pneumococcus in that natural incubator, the mouth and upper air passages. What is more likely than that a considerable quantity of antibodies is formed and some degree of immunity set up as a result of the continual absorption of small doses of the toxins and other metabolic products of the pneumococcus. It is not surprising to find that the opsonin content of normal human serum is on an average double that of the normal rabbit, although it must be borne in mind that opsonins probably form but one of many antibacterial substances elaborated by the body in its unceasing resistance to the attacks of external forces. Assuming the opsonin present in the normal human serum to be represented by unity, the opsonin in the normal rabbit serum only reaches half that figure. The figure expressing that ratio—viz., 0·5—is spoken of as the opsonin index. By the exercise of infinite care, however, in the process of immunisation the pneumococcus opsonin content of the rabbit's serum may be raised until it is equal to, and even greatly superior to, that of normal human serum. Under these conditions the injection of the pneumococcus of sufficient virulence and sufficient dose to cause the death of a control rabbit within 36 hours from acute septicæmia will only give rise to localised suppuration.

that it can no longer be regarded as a "one compartment" organ. (I am very greatly indebted to Professor Cunningham for permission to publish several of his illustrations. I should like to say that practically the whole of this paper had been written before I knew of Professor Cunningham's excellent work, and I was gratified to find that his anatomical observations supported so strongly the deductions I had made from personal clinical observations.) Tracings of x ray shadows of the stomach of "normal" individuals who have taken meals mixed with bismuth subnitrate, made by Cannon and Blake[6] and lately by Pfahler,[7] show the differentiation indicated so well by Professor Cunningham, although these authors do not point this out. The "normal" stomach when at rest—i.e., empty—appears, to judge from these anatomical studies, to be tubular in nearly its whole extent, the exception being the proximal, larger part of the cardiac end, which never loses a more or less saccular form. Judging from what one sees on "screening" a stomach which is disposing of a bismuth meal this *normal* form becomes even more marked than in the resting state. This *normal* form of the stomach is seen in its most perfect condition in the stomach of the fœtus before term. (See Figs. 2, 3, and 4.)

Having been impressed (from clinical observations) with the idea that the adult human stomach in its natural state should more or less conform to this type, I naturally looked for confirmation in the formalin-hardened stomachs investigated by Professor Cunningham, and, to my mind, it is not wanting. One must remember, in looking at his illustrations, that the hardening fluid was probably never injected earlier than 24 hours after death. By this time gas formation occurs. This causes irregular relaxation of the gastric walls. In one case one part dilates while another remains contracted; in another case the reverse occurs, and so on. The onset of death and the loss of contractility of unstriped muscle, in the case of arteries, varies with the condition of the individual's nutrition at death. This rule, no doubt, applies also to the unstriped muscle of the alimentary canal and must be taken into account when such observations are made. Thus an average must be struck in order to arrive at an approximately

[7] Journal of the American Medical Association, Dec. 21st, 1907.

upon temperature and upon the pulse and respiration rates; in one case it appeared to have no effect whatever, and in the last case it was powerless to avert the fatal issue. Pane, in reporting 29 cases with two deaths and a further series of nine severe cases of epidemic pneumonia (in Naples) with one death, insists on the rapid improvement that follows the injection of serum.

Antipneumococcic serum has, however, nowhere achieved the striking results in acute infections that are associated with the serum treatment of diphtheria, and it has never obtained the confidence of the profession, while in chronic and suppurative pneumococcus infections the serum is quite useless. There are many reasons for its failure. In the first place, the pneumococcus elaborates but very feeble toxins *in vitro*, and the serum which is obtained from immunised animals is antibacterial only and not antitoxic, hence it would appear probable that its administration would only be effective during the very early stages of infection or in cases of pneumococcic septicæmia. But the symptoms develop in man and the diagnosis is made only when the pneumococcus has obtained a firm foothold; consequently to be of value a very powerful bactericidal serum is needed and experimentally at least the capacity to protect against some 300 minimal lethal doses per cubic centimetre of serum is the most powerful yet available. Many of the symptoms observed in pneumococcic infections are, moreover, those of profound toxæmia and a purely bactericidal serum would appear to possess very little therapeutic value in such circumstances; on the other hand, Pane states that though his serum is bactericidal it does not act directly upon the pneumococcus itself but produces its beneficial effects by establishing a true active immunity. Then, again, Washbourn and I elicited the fact that varieties exist among strains of pneumococci which can only be appreciated by the failure of the serum to protect animals infected with them, for in testing Pane's serum we found that it protected against four out of five of our strains but was absolutely powerless against the fifth. Finally, the various brands of serum vary considerably, even in their bactericidal power, probably owing to the fact that the bleeding of the immune animal is usually carried out at a date determined by purely clinical observation, and it is just possible that if the animal's blood was examined daily and the amount of some antibody—say, pneumococcus opsonin—estimated and the bleeding performed when that body was present in maximum quantity, vastly superior clinical results might follow the administration of such serum.

Turning now to the employment of killed cultivations or vaccines in the treatment of pneumococcus infections a much greater measure of success is obtained. The behaviour of acute infections such as septicæmia and lobar pneumonia under the influence of pneumococcus vaccine has not yet come under my own personal observation, but excellent results in this direction are reported by American observers. I am, however, firmly convinced of the value of vaccines in the chronic suppurative lesions due to the pneumococcus.

In our early studies of experimental infections with the pneumococcus Washbourn and I had observed the fact that when immunising rabbits by the method I have already described the healing of the subcutaneous abscess which followed the inoculation of the first dose of living pneumococci could be accelerated by a subcutaneous or an intraperitoneal injection of killed broth cultivation; indeed, in some instances, if the injection was made before definite fluctuation could be detected in the local lesion, the process of tissue necrosis was arrested and resolution took place. These happy results were not always attained, the reason, of course, being that we had no reliable guide as to when and how much to inject. I have already stated that a correct appreciation of the movements of the opsonin index forms the basis of, and renders possible, the treatment of bacterial infections by means of killed cultivations of the responsible organisms, or, more shortly, "vaccines," and

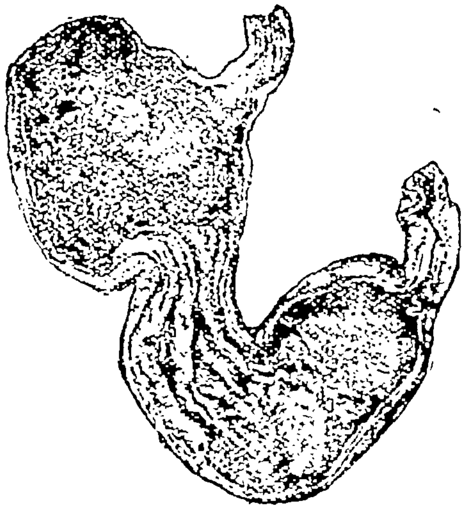
The arrows indicate the days when injections of pneumococcus vaccine were administered.

tubular distal part is capable of peristaltic action as well (Figs. 12 and 13). The action of the oblique fibres (Fig. 14) would materially aid the sphincter aditus vestibuli. The pyloric part of the stomach is normally tubular, tonically contracted, and at certain stages of gastric digestion affected by strong peristaltic waves which increase in strength as the pylorus is approached, corresponding to the increasing amount of circular muscular tissue present. All this is easily confirmed by the use of x ray screening after a "bismuth" meal. The meal (containing from 1½ to 2 ounces of bismuth subcarb.) should be taken in two or three "courses" at intervals of from 15 to 30 minutes.

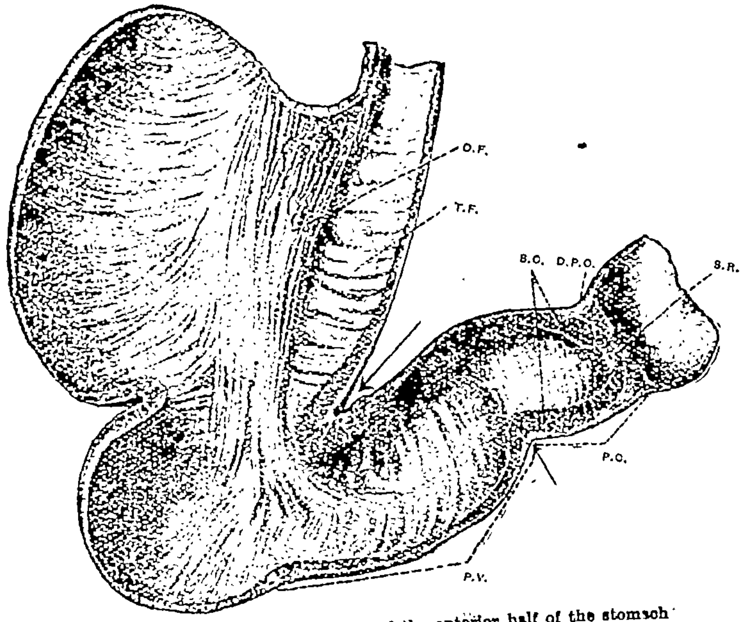
FIG. 13.



"The anterior half of the stomach depicted in Fig. 11." (Cunningham).

The pyloric portion, as I shall point out again later, thus resembles a much-hypertrophied piece of intestine, the hypertrophy becoming more marked as the pylorus is neared. There is no good reason for thinking that reversed peristalsis should occur here any more than in the small intestine. If the pylorus is closed an axial reflux stream takes place (not necessarily back into the cardiac end).[10] Yet the common idea seems to be that food is tossed or churned backwards and forwards in the stomach as a whole. It may quite reasonably be supposed that when food enters the easily dilated cardiac portion it becomes mixed with "juices" secreted there and is passed on from one compartment to another as soon as it is suitably prepared. If too much food is introduced some of it is ejected (vomited)—e.g., in the presumably normal stomach of the infant. If unsuitable food is taken abnormal secretion occurs—e.g., too much acid. This *may* be neutralised in the pyloric portion; if not, the pylorus is irritated and remains contracted, regurgitation into the cardiac end occurs, and a "vicious circle" is established and maintained till the stomach is emptied by vomiting and a fresh start can be made. This very readily occurs in the infant. In these modern days, as the individual grows older, the stomach becomes increasingly abused, the "natural" state of things is changed, and a larger and larger part of the cardiac end goes to form the passive reservoir. When the cycle of events has led to actual disease (ulceration, pyloric spasm, stenosis, &c.) more and more of the stomach is involved till it assumes the condition of a large flaccid bag which has little power of emptying itself. There are nowadays very few normal stomachs to be found. In fact, it is probable that the "normal" condition in the adult is, as I have indicated, a rather feebly acting cardiac bag and a more forcibly acting, but still too frequently relaxed, pyloric tube. Such an organ is very easily upset in its digestive powers.

FIG. 14.



"This figure shows the muscular fibres of the anterior half of the stomach represented in Fig. 10. The mucous membrane and submucous coat have been removed from the interior." (Cunningham.)

The juices secreted by the different parts of the alimentary tract interact upon one another, stimulating or inhibiting. For example, as Wertheimer and others have shown, acid in the duodenum excites the production of secretin, which in turn stimulates the secretion of pancreatic juice. This observation applies apparently to the greater part of the small intestine, although the response is more feeble in the lower parts. On the other hand, according to some authorities, secretin or some other substance in the small intestine exerts an inhibitory effect on the secretion of the gastric (acid) juice. If, then, owing to hyperacidity, pyloric spasm occurs the gastric juice cannot gain access at the proper time to the small intestine and the cycle of events referred to is broken. The effect of gastro-enterostomy, by draining the pyloric portion through the short circuit, is to act as a safety valve. A more probable explanation, in the light of the opinion of the greater number of physiologists, is the following. In a case, for example, of hyperacidity causing pyloric spasm mere drainage of the pyloric portion removes foodstuffs which serve as a chemical stimulus in the production of acid and also provides for easy escape of the excess of acid tending to be present. Therefore the hyperacidity will be reduced and consequently the pyloric spasm. As Starling[11] remarks: "The juice secreted in the second phase must vary according to the quantity of gastric hormone produced in the pyloric mucous membrane, and therefore with the nature and amount of the substances produced in the preliminary digestion of the gastric contents by means of the psychic juice. ...... The second phase of secretion will continue so long as there are substances present in the stomach to act upon the pyloric mucous membrane." Draining off these will necessarily diminish the production of juice.

---

[10] Since this paper was submitted for the acceptance of the Editor of THE LANCET I have read with great interest the valuable article in the *British Medical Journal* of Jan. 18th, 1908, p. 134, by Dr. A. F. Hertz. I quote one paragraph which has a very direct bearing on what I have said: ' No mixing of the contents of the two parts of the stomach occurs. Thus, on a number of occasions I have observed that if food mixed with bismuth carbonate is eaten shortly after a meal containing none of the salt, a rounded shadow just under the left half of the diaphragm is seen, whilst the pyloric part of the stomach remains invisible. After some time the first part of the meal passes into the duodenum, and the food containing the bismuth gradually replaces it in the pyloric part of the stomach, which therefore becomes visible."

[11] Loc. cit., pp. 78, 79.

this holds good in the case of infections by the pneumococcus, and particularly those which are localised and are associated with pus formation. Cases such as these have yielded most promising results and I could cite numerous instances. I have, however, selected two which will suffice to show the possibilities of this adjunct to ordinary operative procedures.

The first (Chart 4) was a small girl in whom double lobar pneumonia was followed by empyemata, that on one side being opened on the twentieth day of the disease and on the other two days later. A subcutaneous (pneumococcic) abscess of the arm was also opened on the twenty-second day. The right hip, the seat of suppurative arthritis, was operated upon on the thirtieth day and an iliac abscess also was drained. On the fifty-fourth day an abscess in the gluteal muscles, behind the trochanter, was incised. A vaccine was prepared from a pneumococcus isolated from the empyema pus and treatment was commenced on the fifty-second day. The effect of the injections upon the temperature is well seen, and the case, which had been regarded as hopeless, was discharged to a convalescent home on the eighty-second day. The next case (Chart 5) suggests the point I have already referred to concerning particular varieties of pneumococci against which certain antipneumococcic serums were powerless. The boy was under treatment for tuberculous peritonitis complicated by a secondary pneumococcic infection, and pus crowded with pneumococci was discharged freely through the ruptured umbilicus. On the twenty-second day after the patient's admission to hospital and again on the thirty-third a "stock" pneumococcus vaccine was injected but without obvious effect so far as concerned either temperature or general clinical condition. A vaccine was then prepared from the particular pneumococcus isolated from the peritoneal pus of this patient and improvement followed the injection of a dose on the forty-fourth day. The improvement was continued, the patient put on weight, the pus gradually disappeared, and the temperature came down. Tuberculin treatment was then adopted and the patient after a short stay in a convalescent home will become an out-patient.

One other application of pneumococcus vaccines to cases in which operative treatment is needed—and these remarks hold equally in the case of other bacterial infections—and I have done. Where the opsonin content of the blood is low the preliminary injection of a suitable vaccine by stimulating the manufacture of further supplies places the patient in the most favourable condition to withstand shock and resist the further spread of infection through the disturbance of the tissues involved by the necessary operative procedures. In illustration I might mention a case of empyema and peritonitis following lobar pneumonia in an adult female under the care of Dr. W. Hale White. From the pus, the fluid portion of which had an opsonic index of less than 0·2, a virulent pneumococcus was isolated, a vaccine prepared, and a dose injected. Two days later the empyema was opened, when it was found that the pleural cavity communicated with the abdominal cavity and some five or six pints of pus were removed. The index of the liquor puris was now 0·9. The patient convalesced rapidly—a few more injections of vaccine were required—and was discharged cured.

CONSIDERATIONS CONCERNING THE FUNCTIONS OF THE STOMACH AND THE OPERATION OF GASTRO-ENTEROSTOMY.

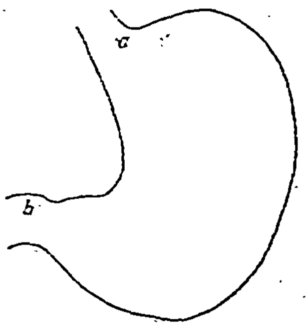
BY H. M. W. GRAY, F.R.C.S. EDIN.,
SURGEON AND LECTURER ON CLINICAL SURGERY, ABERDEEN ROYAL INFIRMARY.

ON account of the usually immediate and striking benefit obtained, the operation of gastro-enterostomy has established itself as a very valuable and necessary procedure in many diseases involving the stomach and duodenum. Nevertheless, in spite of careful selection of cases, disappointing results, such as regurgitant biliary vomiting or formation of jejunal ulcer perhaps with perforation, occur occasionally, even when the most modern method (posterior no-loop) has been followed. Why such sequelæ should occur only occasionally, when apparently the same technique has been carried out as in perfectly successful cases, is not clear. A possible explanation may be that sufficient care is not taken in the selection of the site of the opening in the stomach. Mayo's guide (that the opening should lie in a vertical line from the cardiac orifice) is probably a thoroughly sound one when the stomach is lying undisturbed in the abdominal cavity. When the stomach is pulled out, however, or otherwise manipulated the proper place may not be chosen, as the organ tends to swing round its lesser curvature. This, as I shall endeavour to show, *may* be the reason of untoward results.

The best operative procedure is that which most nearly preserves or restores the natural functions of any part requiring such interference. For this, of course, accurate knowledge of the natural functions of the part concerned is necessary. I venture to assert that this essential is not fulfilled in the case of the stomach, at least in so far as its motor functions are concerned.

It would seem that gastric surgery, as developed from experience gained in earlier operations on greatly dilated stomachs, has persisted in regarding the stomach as a "one compartment" organ. (Fig. 1.) Operations were planned with the object of "draining" these huge stomachs. To suit latter-day ideas some other term than "drainage" must be found. It does not convey a proper idea of the modern operation, which is executed more on the principle of a "short circuit" or, in some cases, of a "safety valve." Cannon and Blake[1] showed that gastro-enterostomy need not be a drainage operation; that, in fact, food preferred to pass through the pylorus rather than through the newly formed "stoma," unless the latter was made very large. Their observations have probably been too much emphasised in this connexion. They were made on normal healthy cats. Leggett and Maury's[2] more recent experiments prove little. Most of their operations, recorded in detail, seem to have resulted, more or less, in the old "vicious circle."

FIG. 1.



Tracing of stomach figured by W. J. Mayo in article on the Technique of Gastro-enterostomy in the Annals of Surgery, April, 1906 (reduced to one-third). *a*, Cardiac orifice; *b*, pyloric orifice.

To procure its beneficial results gastro-enterostomy *must* be at first a drainage operation; later, when the gastric secretions and the condition of the pyloric sphincter and of the neighbouring mucous membranes have become more normal, this function of drainage is not required and food *may* again pass naturally through the pylorus. Where permanent pyloric or duodenal stenosis is present, then, of course, "drainage" is permanent. Cannon and Blake[3] have shown that towards the end of digestion the pyloric end of the stomach is the lowest part, owing to the contraction of the longitudinal fibres of the stomach, and therefore that the "stoma" in gastro-enterostomy should be made as near the pylorus as possible. This seems rather at variance with their finding, that the operation is not a drainage one, and I shall endeavour to show that there are probably more potent reasons why the "stoma" should be made as near the pylorus as possible. The great reason is that by making the stoma in this situation gastric digestion is allowed to become more quickly and permanently normal again.

Professor D. J. Cunningham,[4] the late Professor Birmingham,[5] and others have shown very conclusively in anatomical specimens that the shape of the stomach is very different from that described until a few years ago. It is evident secretion is profuse and renders the chyme more fluid. Hyperacidity of the gastric contents causes irritation or ulceration, especially if they are retained long in this portion by spasm of the pylorus. The pyloric secretion may be insufficient to neutralise this hyperacidity and make the chyme of a proper reaction to stimulate relaxation of the pylorus. Exacerbation of the pain in gastric ulcer is due to irritation thereof by food, acid, or more or less by increased movement. In support of the foregoing statement (at the end of the last paragraph) I point out that the pain of ulcer of the pyloric region does not assert itself until a considerable interval after food is taken into the stomach, i.e., until some part of it, first rendered acid, has gained access to the pyloric part. If the pain is due to increased movement of the pyloric part, then this portion must be at rest during the earlier stage of gastric digestion (tonically contracted).

[3] Loc. cit.

[4] Transactions of the Royal Society of Edinburgh, vol. xlv., Part I., No. 2.

[5] Cunningham's Text-book of Anatomy, second edition, p. 1052.

It seems that the mechanical functions of the stomach, as hitherto understood, have been deduced (1) from imperfect anatomical knowledge; (2) from direct observation (Rossbach) perforce made under abnormal conditions; (3) from chemical tests made with substances which are absorbed only when they reach the duodenum; (4) from the persistence in the stomach after varying periods of indigestible particles or ordinary food-stuffs introduced; and (5), possibly most important, from x ray screening of the stomach after a meal mixed with bismuth. Of these, only (2) and (5) may throw light on the action of the pyloric portion; (3) and (4) have reference to the action of the stomach as a "one compartment" organ. With regard to Rossbach's observations, as already stated, one often sees contraction of the pyloric portion in a fasting stomach exposed during operation. The churning action, observed at an early stage and attributed by some x-ray observers to the pyloric portion, is apparently confined to the part of the cardiac portion adjacent to the "sphincter aditus vestibuli," which is possessed of peristaltic action.

Physiologists state that the "two portions of the stomach seem to be partially or, in certain animals from time to time, completely cut off from each other by the contraction of the sphincter of the antrum" (Stewart). The part distal to this "sphincter" is in the living stomach tubular (Starling). An obvious difference in colour of the parts of the stomach is apparent in such an animal as the rat. This is sharply demarcated.

Developmentally, the greater part of the cardiac end of the adult stomach is a mere diverticulum, blown out, as it were, from one side of the gastric tube, although it is the most important part of the tube from the standpoint of the gastric digestion.

The predisposition of the pyloric portion to ulceration as compared with the cardiac end has already been referred to. The constriction in cicatricial hour-glass stomach usually occupies the site of the "sphincter aditus vestibuli." The part of the cardiac portion adjacent to the lesser curvature (the remnant of the gastric tube from which the cardiac diverticulum is developed) is to be differentiated from the rest of the cardiac portion. It resembles the pyloric portion and is the usual site of ulceration when this involves the cardiac end.

Thus developmentally, anatomically, physiologically, and pathologically, there are great differences between the pyloric and cardiac ends of the stomach.

Taking these differences into consideration, it seems extraordinary that the stomach should be looked upon, for working purposes, as a "one compartment" organ. Indeed, it seems absurd to suppose that food was meant to be tossed about inside an organ which pours out acid secretion at one end and alkaline secretion at the other end. It would be folly
the one type of secretion does not inhibit the
other by mere neutralisation alone. That a gour-
extreme digestive disturbance even although he
his stomach so that cardiac and pyloric portions
proves merely the extraordinary accommo-
human alimentary tract—it does not dis-

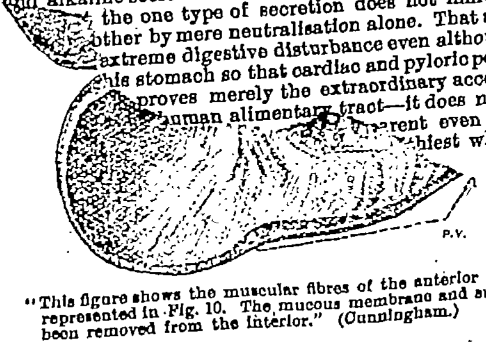
in



"This figure shows the muscular fibres of the anterior half of t
represented in Fig. 10. The mucous membrane and submucous
been removed from the interior." (Cunningham.)

The opening in the operation of gastro-enterostomy must be made as near the pylorus as will permit of a "comfortable" position of the duodeno-jejunal portion to be anastomosed. By fixing this portion to the stomach in a more antero-posterior line than is usually done one finds that the opening can be made an inch or two nearer the pylorus.[13] (Of course there must be no kink formed in the upper part of the bowel.) This margin may make all the difference afterwards.

The opening should be a large one, as I think it is of great importance that it should *provide "drainage,"* when this is necessary, not of the cardiac portion but *of the pyloric portion*, and thus allow exit into the jejunum of the hyperacid gastric contents when projected into the pyloric from the cardiac end. This will at once place the pyloric end practically at rest compared with its previous restlessness in attempting to overcome the resistance of the irritated and spasmodically contracted pyloric sphincter. The tendency to prolonged acidity in the pyloric end will be neutralised by "the entrance of the alkaline pancreatic juice and bile" (Paterson).[14] These two factors explain the usually immediate cessation of the severe pain of ulceration after gastro-enterostomy.

The escape of the acid chyme is not prevented by the pyloric sphincter and takes place into the jejunum through the new stoma at an early period and will stimulate pancreatic secretion at an earlier stage than previously occurred in the patient. As Mr. H. J. Paterson points out, there will then be a correspondingly earlier diminution of the gastric secretion and therefore the hyperacidity will be reduced. The early escape of foodstuffs from the stomach by diminishing normal chemical stimulus might account in large measure for this, as previously pointed out. The "abnormal excitation of the gastric mucosa which results from spasmodic stenosis of the pylorus" (Paterson) will of course be done away with.

I believe that the tonic contraction of the pyloric portion and of the sphincter aditus vestibuli is the usual and essential factor in preventing regurgitant biliary vomiting. The action of the muscular coats of this part is stronger than that of the jejunum, hence will prevent any more than a very localised escape of bile and pancreatic juice into the stomach, unless placed in such impossible conditions of vicious circle as the frequent kinking in the old loop method produced. In uncomplicated cases of gastro-enterostomy I have found, on passing the stomach tube, that bile is not present in the cardiac end of the stomach.[15] If the passage of the tube causes attempts at vomiting it is quite probable that the increased intra-abdominal pressure, especially in cases where dilatation existed previously, will cause regurgitation of bile and pancreatic juice into the cardiac end. I believe that the cases of biliary vomiting which I have heard of occurring after the no-loop method are probably due to the fact that the anastomotic opening has been made in the cardiac enlargement where the bile probably causes irritation and is vomited. In certain cases, of course, it is no doubt due to malposition of the anastomosed bowel. Even when the opening has been made in the cardiac enlargement, the muscular action of the cardiac end may keep or force back bile into the jejunum and thus prevent vomiting, but in cases of atony of this part the bile and pancreatic juice may follow the line of least resistance, fill up the cardiac end, and be vomited. Mr. Moynihan's case,[16] in which the whole of the bile and pancreatic juice had to pass back through the pylorus owing to the operative closure of the duodenum, does not necessarily prove that bile is non-irritating to the stomach. He does not record to what portion of the stomach the jejunum was attached—probably to the part presenting in the wound (the pyloric portion), in which case the bile would pass almost immediately into the jejunum. All the same, in many cases, "bile" in *small* quantity does not appear to cause irritation in the cardiac end. When fatty food is taken in excess the accurate knowledge of the condition of affairs. One expects, of course, that where circular muscular fibres preponderate, there constriction will more frequently be present. By making a composite picture therefore of the illustrations presented by Professor Cunningham one finds that the fœtal form asserts itself. (Figs. 5 to 11.) Observations on the stomach form (such as those made by Wernstedt[8]) when even artificial distension (*künstliche Dilatierung*) was often made previously to the hardening process are obviously of no value in settling this question.

---

[13] On the eve of sending this paper for publication I have read Mr. B. G. A. Moynihan's article on "The Treatment of Chronic Diseases of the Stomach," Surgery, Gynæcology, and Obstetrics, January, 1908. In it he advocates this "vertical" position of the jejunal loop.

[14] THE LANCET, Sept. 21st, 1907, p. 815.

[15] I have obtained stomach contents (from two to four hours after a meal) from six cases operated on during the past six months. The specimens were examined by Dr. J. M. Macqueen in the Physiological Department, Aberdeen University. In five there was no trace of bile. (In one of these the attempt to pass the stomach tube caused vomiting.) In one there was a very faint trace of bile. In this case, pericolonic adhesions, found at operation, may have caused slight obstruction in the efferent loop of jejunum.

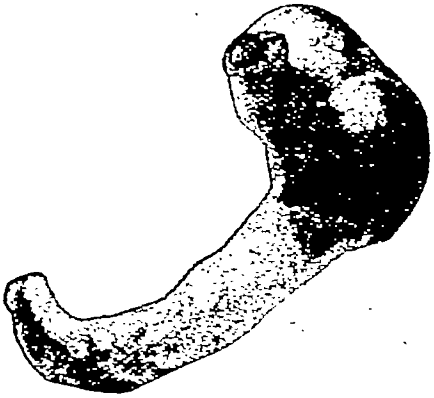
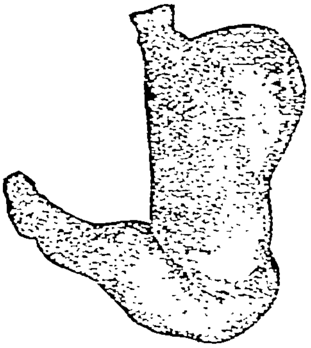
FIG. 8.



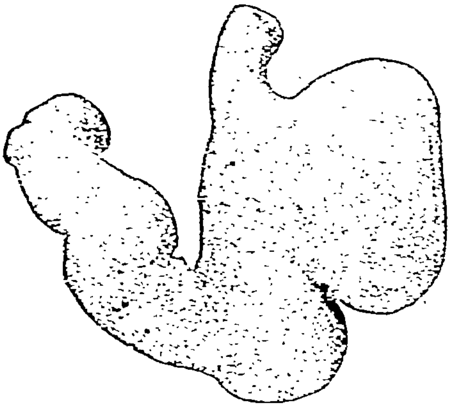
"Stomach of a young adult male viewed from above, in which the emptying process is nearly completed." (Cunningham.)

FIG. 9.



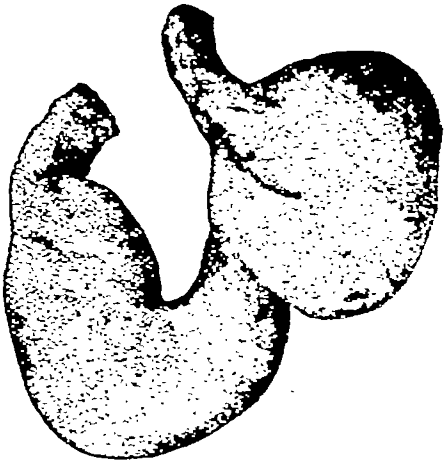
"Stomach of an adult female; aberrant form." (Cunningham.) May not this be merely modified by post-mortem dilatation?

FIG. 10.



"Stomach of an adult male; aberrant form." (Cunningham.)

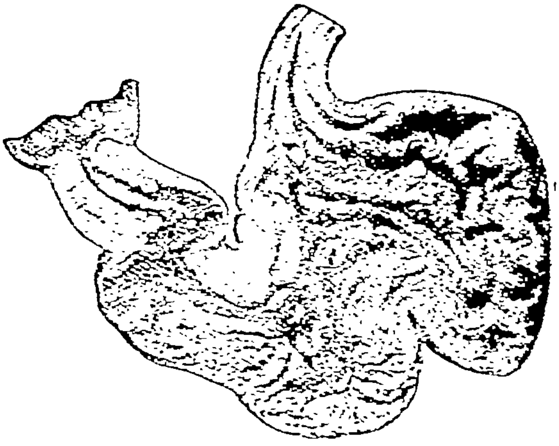
FIG. 11.



"Specimen obtained from the post-mortem room. It exhibits a form intermediate between that seen in Fig. 7 and that of a true hour-glass stomach." (Cunningham.) Might not post-mortem dilatation explain the difference in appearance?

The stomach is divided by the so-called "incisura angularis" (His), on the lesser curvature, into a more or less vertical cardiac part, to the left, and a horizontal pyloric part to the right. As stated, the proximal part of the cardiac portion is always sac-like. The distal part is well supplied with circular fibres. Into the far end of this numerous bands of oblique fibres run from the cardiac orifice (Fig. 14), reaching to the greater curvature opposite the incisura angularis. These are quite well marked and have no doubt a definite function to perform. This tubular (?) cardiac part deserves greater attention than it has hitherto received, as it is probably in it that most important preliminary "churning" of the food takes place. (Figs. 12 and 13.) The food is thus thoroughly mixed with the cardiac juices before being passed into the pyloric part. The "incisura angularis" corresponds in many specimens with a well-marked set of circular fibres (Figs. 12 and 13) previously known, by physiologists especially, as the "sphincter of the antrum" or the "transverse band." According to Starling[9] this is a physiological and not an anatomical sphincter. I suggest that "*sphincter aditus vestibuli*" is a more suitable name. The pyloric portion of the stomach is subdivided by a slightly marked sulcus on the greater curvature into a larger part, the *pyloric vestibule*, and a smaller, very muscular part, the *pyloric canal*.

FIG. 12.



"Section through the stomach of an adult male (aberrant form) along the plane of the curvatures." (Cunningham.)

The proximal sac-like part of the cardiac portion is endowed apparently only with tonic contraction. The more of parents play some considerable part. In reality the chorio-capillaris of the choroid seems to be first attacked, the retinal degeneration being secondary. As you are aware the outer layers of the retina are nourished by the chorio-capillaris and in retinitis pigmentosa the inner layers show comparatively little change. These facts help us to a reasonable conjecture as to the exact causation of the night blindness.

[8] Archiv für Anatomie und Physiologie (Anatomische Abtheilung), 1907.

[9] Recent Advances in the Physiology of Digestion, by E. H. Starling, 1906, p. 134.

You will remember that in birds which seek their prey at night, such as the owl, the retina contains only rods; there are no cones in the neuro-epithelial layer. You will also remember that the visual purple is associated with the rods only, so that in animals possessing a fovea, where the rods are absent, there the visual purple is also absent. I may further remind you that with low illumination in man there is much more rapid depreciation of central than of peripheral vision, so that we may reasonably conclude that vision in these circumstances is chiefly carried out through the agency of the rods. Form sense, dependent upon the cones, quickly diminishes in passing from the point of fixation towards the periphery, but at night acute appreciation of variations of light and shade is much more important than accurate delineation of objects. These considerations may afford some explanation of the night blindness in retinitis pigmentosa, as well as of the partial nature of the annular scotoma and the comparative perfection of central vision. Of course, it is not suggested that the cones escape destruction in the affected zonular area, but their loss is discounted by their relatively unimportant functions in this situation.

There is another chronic form of night blindness which we occasionally meet with, differing from retinitis pigmentosa in the fact that it is stationary. This form is always hereditary and shows no gross changes in the fundus. It is a rare disease except in the families afflicted with it, when as has been recently shown in a very striking manner a large proportion of the members are attacked. Thus Mr. E. Nettleship has continued the work of Cunier on a certain family in the south of France and has discovered no less than 135 subjects of congenital night blindness amongst 2121 members of 10 generations, the first member of which, a male, himself night blind, was born in 1637. Unfortunately, no case of this disease has been examined anatomically; it may possibly be found that the retina is deficient in rods or visual purple.

A group of cases of chronic night blindness in some respects intermediate between idiopathic retinitis pigmentosa and congenital night blindness is that of syphilitic pigmentary retinitis. It does not show the same uniformity either of symptoms or of objective signs that are characteristic of idiopathic retinitis pigmentosa. The night blindness is progressive during the active stage of the disease but may then remain stationary for an indefinite period. Fundamentally, however, the night blindness must be regarded as due to the same pathological processes. Besides these chronic forms of disease manifesting this symptom there are also acute forms. Though these show a great variety of clinical types there is nearly always one feature common to all—namely, malnutrition. They are probably much less frequently seen in England now than formerly owing to the improvement in the conditions of the poor. We generally meet with them in badly nourished children and a large proportion of them have xerosis of the conjunctiva. The combination of these symptoms is not so invariable as is sometimes thought. Many cases of xerosis without night blindness and *vice versâ* occur. In some cases the cornea becomes ulcerated and in the worst there is keratomalacia; in many of these the age of the patient or the severity of the attendant symptoms prevents the demonstration of night blindness. One fact which may be definitely deduced is that there is no inherent relationship between the xerosis and the night blindness other than a common cause.

Acute night blindness was at one time common among sailors, soldiers, and the inmates of prisons and workhouses. In Russia it was, and probably still is, common during the Lenten fast. Uhthoff, amongst 500 cases of severe alcoholism, found 5 per cent. suffering from xerosis, night blindness, or both together. Less frequently night blindness has been found associated with scurvy, malaria, nephritis, the puerperium, vegetarianism, and so on. Most of these patients have reflex blepharospasm ("photophobia") in bright sunlight. That in many, most likely all, the lesion is peripheral is shown by Mr. Nettleship's interesting observation that if a sailor afflicted with the disease covers up one eye during the daytime that eye has sufficiently good vision at night for the man to carry out the duties of the watch. It would appear, therefore, that malnutrition acts by lowering the vitality of the retina in such a manner that the process of repair is delayed. Probably the visual purple is restored more slowly than normal—that is, the anabolic processes are defective. To call the condition torpor retinæ and to regard this as an explanation is futile; it is simply describing the condition by another name.

Another group of cases of night blindness, allied to those last mentioned but deserving separate treatment, are those associated with jaundice. The symptom is not very uncommon in severe cases of jaundice. In some pigmentary changes of slight degree have been found in the retina and the condition has been dignified with the name ophthalmia hepatica: in most the ophthalmoscopic signs are negative. It is noteworthy in this connexion to recall the fact that bile salts are a solvent of the visual purple, as was shown by Kühne. Night blindness is common in India among badly-nourished natives, especially during the periodic famines. It has been found that the symptom disappears when the patients are fed on liver, a fact difficult to correlate with the cases occurring with jaundice. The mode of treatment is of extreme antiquity, being advocated in the *Ebers papyrus* (B.C. 1500).

A CASE OF ANEURYSM OF THE FEMORAL ARTERY IN A MAN, AGED 78 YEARS,

IN WHICH SUPPURATION TOOK PLACE FROM PNEUMOCOCCAL INFECTION; RECOVERY.

BY H. H. CLUTTON, M.A., M.B., M.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO ST. THOMAS'S HOSPITAL;

AND

LEONARD S. DUDGEON, M.R.C.P. LOND.,

BACTERIOLOGIST TO ST. THOMAS'S HOSPITAL; JOINT LECTURER ON PATHOLOGY IN THE MEDICAL SCHOOL.

FOR the history and many details of this case we are indebted to Dr. A. Bevan who attended the patient throughout his illness.

The patient was an old man, aged 78 years, living in a hotel who was suddenly taken ill with a rigor and a temperature of 104° F. on Jan. 18th, 1907. He had a cough and rapid respiration but there were no signs in his chest until two days after the onset of his illness. Consolidation of the upper lobe of the right lung was then found. This was followed by a patch of dulness at the angle of the left scapula and at the right base. The temperature touched normal on the third day of the illness and then fluctuated between 100° and 103·4° until the eighth day, when there was a pseudo-crisis with a rise next day to 101·2°. It then fell again on the tenth day to 96·4°. The temperature fell to 96·4° three times with intervening slight rises to 97·2°, remaining subnormal for the following ten days. There was a very dangerous collapse during this time. The pulse-rate fell from 98 to 60, and sometimes could not be counted, as many beats failed to reach the wrist. The heart sounds were very faint from the combined effect of emphysema and feeble action but no cardiac murmur was heard at any time during the illness. The expectoration was of the "prune-juice" type rather than rusty. Dr. H. G. Turney, who saw the patient in consultation with Dr. Bevan, reports that "the pneumonia was clinically on the whole of the influenza type, though the termination was by crisis. The physical signs varied a good deal from day to day; there never was really massive consolidation and he sweated a good deal all through the attack." The patient remained in a low and feeble condition with a subnormal temperature until Feb. 10th. He then improved and the temperature became normal, but from the 20th onwards evening pyrexia (99°) was constant. There was also at this time a little swelling of the left leg and foot from œdema, and a local swelling was noticed about the middle of March in the course of the femoral vessels which was thought to be due to thrombosis of the left femoral vein. In April Dr. Bevan found that this swelling pulsated and regarded it as an aneurysm. Towards the end of April it began to increase in size and the pulsation appeared to be nearer the surface. On examination it was found to be a large swelling situated in Hunter's canal on the left side, with inflammatory exudation into the tissues around, or the aneurysm may even then

I feel that this view of the anatomical arrangement of the adult stomach is the right one owing to the fact that I have so frequently observed this condition of affairs during operations on or near the stomach. As I have stated already, one finds that, unless the stomach is much dilated as a whole, the pyloric part when exposed, and especially if handled, looks like a piece of much hypertrophied intestine. This part presents in a median epigastric incision. The cardiac part is usually flaccid. In cases where gastro-enterostomy has been indicated I have found it enlarged as well as flaccid. Indeed, the presence of this *flaccid enlargement may be an indication that gastro-enterostomy will do good, even although no pyloric stenosis exists*. This cardiac portion does not appear in the wound, but when pulled out makes a striking contrast to the contracted pyloric part and offers great temptation to those who believe in the "drainage" qualifications of gastro-enterostomy, to make the stoma at the most dependent part of the flaccid bag. Moynihan[12] refers to repeated observations of localised spasmodic constrictions "in the body of the stomach and at the pylorus, but never at the fundus." These I have also observed. They are, of course, quite different from the general contraction of the pyloric portion which I have just described. In fact, they may occur along with this, especially if the stomach be mechanically irritated.

FIG. 15.

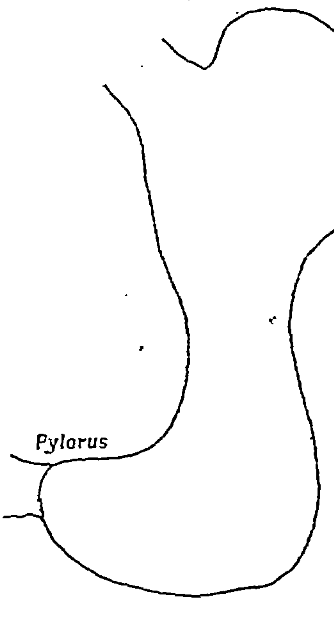

FIG. 16.

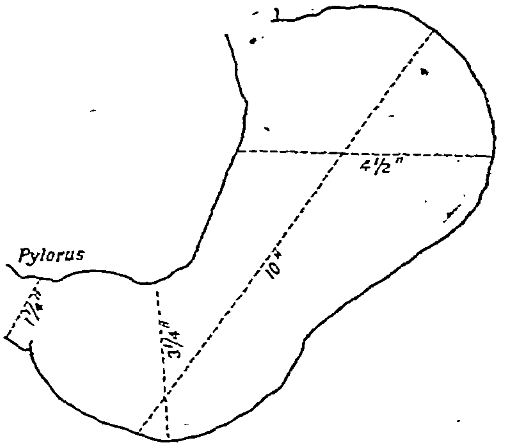

FIG. 17.

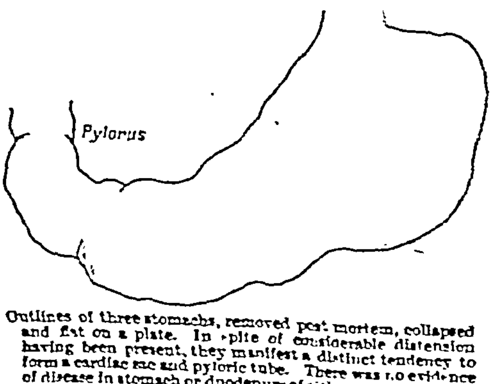

Outlines of three stomachs, removed post mortem, collapsed and flat on a plate. In spite of considerable distension having been present, they manifest a distinct tendency to form a cardiac sac and pyloric tube. There was no evidence of disease in stomach or duodenum of either case. Observed, without selection, by Dr. G. M. Duncan, Pathological Department, Aberdeen University.

It seems to me that our ideas as to what constitutes pathological dilatation of the stomach must be revised. Without doubt such dilatation occurs first in the cardiac end and may be the cause of such persistent symptoms as only operation will satisfactorily get rid of. Our present diagnostic methods of inflating the stomach are ordinarily probably too vigorous and too much attention is given to the relation of the stomach (the pyloric portion, which may still be approximately normal) to the umbilicus. Unless gastric resonance, as ascertained in the neighbourhood of the mid-line of the abdomen, reaches nearly to, or beyond, the umbilicus, there is thought to be no dilatation of the stomach. From practical experience I feel sure that more attention should be given to the condition of the outline of the cardiac portion. Careful external examination will often reveal an unexpected amount of dilatation there. The more natural the stomach the more decidedly is it in the form of "cardiac sac and pyloric tube." This may prove of much value in diagnosis.

In order to explain satisfactorily the symptoms of gastric ulcer and the beneficial effects of gastro-enterostomy the cycle of events in the stomach at work must be somewhat as follows. The cardiac portion acts as a reservoir, in which food is, in a great measure, prepared for further digestion by being subjected to the action of the juices secreted in that part. The food is intimately mixed with those juices by the churning action of the gastric muscular coats, especially of the distal part of the cardiac portion, and by the movements of the diaphragm and abdominal muscles during respiration and conversation, and still more so during forced respiratory movements, such as laughing, sneezing, and the like. (This can be confirmed by screening after a bismuth meal.) Hence we have possibly a partial scientific explanation of the adage, "laugh and grow fat," and of the custom still extant in some quarters of passing round the snuff-mull at the end of a meal. These movements, moreover, assist the circulation of the blood in the abdominal cavity and thereby are beneficial to digestion. The food, having acquired its proper chemical reaction is now (after from 15 minutes to half an hour, according to the nature of the food), by the drawing up of the greater curvature (Cannon), propelled into the pyloric portion which, by its marked peristaltic efforts, thrusts the food towards and through the pyloric sphincter. Skiagraphic tracings of the human "normal" stomach (e.g., Pfahler's) show that the part well to the left of the mid-line is filled with food first (i.e., the saccular and tubular parts of the cardiac portion—the vertical portion of the stomach). This can easily be confirmed. Even when a considerable quantity of food has been swallowed, causing a fair amount of distension, the vertical cardiac portion is still alone affected. It would seem probable that until the time when the drawing up of the greater curvature takes place there is no food or acid secretion in the pyloric part, ingress of such being prevented by its tonic contraction and higher elevation and the closure of the "sphincter aditus vestibuli" (tucked up by the action of the oblique fibres). A well-marked notch can frequently be seen (with the fluorescent screen) on the greater curvature, corresponding to the position of this sphincter, after part of the "bismuth" meal has passed into the pyloric portion.

The pyloric portion resembles the duodenum in its pathology. The reaction of its secretion is alkaline. Its on several occasions with Dr. Bevan, saw no reason to suspect infective disease of the endocardium. There were no cardiac murmurs during the whole course of the illness. The pyrexia at one time corresponded to the attack of acute pneumonia and later followed the course of the acute infection of the femoral artery. As soon as the suppuration was relieved the temperature fell to normal and has remained normal ever since, except for slight pyrexia which lasted for a few days during the period of convalescence.

---

[12] Brit. Med. Jour., Feb. 20th, 1904, p. 413.

An acute embolic aneurysm which develops during the course of acute infective endocarditis is characterised by its rapidity of formation, and also by a considerable amount of pain at the seat of infection. It cannot be said that either of these phenomena was present in the case under discussion. Perhaps the most important argument against infective endocarditis is that the patient continues in good health and shows no evidence of cardiac disease. The other explanation which we have already referred to is that the patient developed an acute pneumococcal infection of an atheromatous patch in the femoral artery. Careful consideration of the facts of the case strongly suggests either direct infection of the artery leading to the formation of an aneurysm or direct infection of an aneurysm which was present previously to the acute illness. In either case the pathology is somewhat similar. The slow and feeble action of the heart, which was such a noticeable feature in the first few days after the crisis, and the alteration in the coagulability of the blood which is so commonly found in such conditions, would favour the formation of thrombosis either in the sac of an aneurysm or over an atheromatous patch in a degenerated artery. It is impossible to say whether acute infection of the arterial wall took place previously to, or subsequently to, the formation of thrombosis. In either case the pneumococcus, which may probably be regarded as the cause of the acute pneumonia, set up an acute arteritis which finally gave way into the surrounding tissues. It is probable that the infection of the tissues took place through the wall of the artery before actual leakage occurred. In any case, whether the aneurysm was primary or secondary, it appears to have been of the sacculated variety, and direct communication between the sac and the vessel was obliterated before the aneurysm was opened. It is unfortunate that it is impossible to say at what period of the patient's life the aneurysm was formed, but at any rate this does not detract from the great interest which centres round such a remarkable condition.

THREE CASES OF POISONING BY CARBONIC OXIDE; ONE RECOVERY.

BY R. SPENCER PEARSON, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H.R.C.P.S.I.,
LATE MEDICAL OFFICER OF HEALTH, WIGAN RURAL DISTRICT.

CASES of poisoning by carbonic oxide appear to me of sufficiently rare occurrence to justify a description of those which recently happened in the workhouse infirmary, Leighton Buzzard, for such a tragedy to take place in the wards of an institution the arrangements of which had been passed by expert engineers is fortunately uncommon and has a special interest.

On the night of Jan. 20th three women retired for the night in a small ward and at 9 P.M. were known to be in their usual health. A fire had been lighted in the stove as on this day the ward had been cleaned and it is probable that the women had closed the only ventilator before going to bed. On the following morning at 7 A.M. a workhouse inmate went to call the women and found them, as she thought, all dead. There was no smell in the room and the gas was burning, and the fire in the stove was still just alight. The three women were lying as if asleep. On further examination one of them, aged 76 years, was found to be alive, the workhouse master, Mr. Swaffield, at once with commendable promptitude performing and continuing artificial respiration, thus most probably saving her life. The other two women, aged 52 years and 47 years respectively, were quite dead. The master sent at once for Mr. L. Worts, the medical officer, to whom I am indebted for my subsequent conduct of the case and for permission to publish these notes.

I was sent for at 10 A.M. on the morning of Jan. 21st and found a woman, aged 52 years, and a woman, aged 47 years, lying dead. The body of the first woman had been removed from the bed to the floor. She was quite dead; some white foam was issuing from the mouth. Her attitude was one of repose and her complexion and lips were fresh and of a bright cherry colour. The body was warm and rigor mortis was hardly discernible. The body of the second woman was on the bed; the face was pallid and she had vomited some pultaceous matter. She lay on her back with her arms folded over her chest; rigor mortis was marked and the body was quite cold. The third woman, aged 76 years, was lying on the floor, totally insensible, the conjunctival reflex being absent. The pupils were equal and of moderate size. She was practically pulseless and was breathing stertorously, the cheeks blowing with each expiration. Respiration was slow (about 12 to the minute), the lips and mucous membranes were bright, and the complexion was clear. Both wrists showed abrasions the result of the continued efforts at artificial respiration, and it was noted that the reddened skin around the wrists had a peculiarly bright hue. As there was no information to go upon, and as there was a suspicion that all three had partaken of the contents of a mysterious parcel left by a visitor, after injecting $\frac{1}{30}$th of a grain of strychnine I decided to wash out the stomach. This was done with warm water and afterwards with weak Condy's fluid till the washing was clear; the washings were first of a coffee-ground colour. I then gave one and a half ounces of brandy through the stomach-tube, and after injection of ether and the application of the interrupted current in the course of the phrenic nerve, after about three hours the pulse improved, the conjunctival reflex returned, and she responded to outside stimuli. Oxygen was sent for but she recovered before it arrived. She was ordered to be fed per rectum with "panopeptone" and by 6 P.M. she was able to take it by the mouth, and she is now out of danger but can remember nothing of what happened.

Realising that the desperate illness of the third woman must be brought about by the same cause which had led to the death of the other two I decided to make a spectroscopic examination of the blood of the living woman and, being fortunate in possessing an excellent stellar spectroscope, used it with most decided results. A drop of blood from the finger was received into a test-tube two-thirds full of normal saline solution and the tube was shaken up; the resulting solution was of a bright cherry colour. On being placed before the slit of the spectroscope there were seen the two absorption bands of CO hæmoglobin most distinctly, and the reaction was unaltered on the addition of ammonium sulphide. Next day I was present at the post-mortem examination made by Mr. Worts. Both bodies presented similar appearances. The blood 30 hours after death was perfectly fluid and cherry-red in colour. The muscles, too, were bright red. There was no blood clot found at all. The mucus membranes were all bright red and the complexion fresh. The stomach of one woman was empty and presented numerous petechial hæmorrhages, and similar hæmorrhagic points appeared in the cerebral white matter on section; the cerebral ventricles were full of fluid. In both cases the lungs were markedly œdematous and the kidneys showed interstitial nephritis; the capsules were adherent. I took specimens of blood from both dead women and examined them as before, with a like result, the spectroscope giving definite evidence of CO hæmoglobin.

The cause of the carbonic oxide in the atmosphere was, on investigation, not hard to find. At first I thought that it must be due to the permeability of red-hot cast iron to gases, but since then I have had an opportunity of examining the stove with the representative of the firm who manufacture them. The stove is of ornamental cast iron with doors in front which can be opened; on the top is a circular aperture covered by an ornamental perforated cap. The stove stands in the room about two feet from the fire-place, which is blocked up. A six inch cast-iron horizontal pipe passes into the brick flue, terminating on its entrance. The flue is a long one leading from the floor below, one flue common to both landings. Inside the stove is a flame baffler, which when rightly set serves to direct the heat into the room and direct the current both from the fire and the chamber at the top of the stove into the flue. Instead of being set thus the baffler was set as shown in the diagram, thus allowing any products of combustion which passed the baffler to come into the room (Fig. 2). The normal mechanism of the pyloric apparatus is evidently in abeyance. Bile and pancreatic juice are allowed to gain their way to the cardiac part in small amount, upon which the fat there is partly digested—a marvellous provision of nature for the benefit of the gourmand.

In the majority of cases I believe that the opening *is* made in the pyloric portion but, so far as I can make out, with no proper, definite precaution to attain that end. The stomach is usually pushed *down* through an opening in the mescolon and, if the pyloric portion is contracted, the cardiac enlargement may easily be substituted for it. The plan, introduced I think by Professor H. Littlewood of Leeds, of pushing the intestine *up* through the hole in the mesocolon and making the junction with the stomach in more normal position (after tearing an opening in the omentum to get at the posterior wall of the stomach), makes it much more certain that the anastomosis is made in the pyloric portion. The thought occurs—Should one make the anastomosis in the cardiac enlargement if ulcer of the cardiac end exists, risking regurgitant vomiting, or making a Roux's (Y) operation right way? Personally, I do not think so. I have followed the usual plan in such cases of cardiac ulceration as have come under my care and the only difference I have noticed is that the pain took longer to disappear than in pyloric ulcer. The explanation of the cure is the same as in pyloric ulcer.

It is quite possible that making the anastomotic opening in the cardiac portion may explain the occurrence of jejunal ulcer after gastro-enterostomy, especially in the old loop or Y operation. The persistent trickle of acid secretion from the cardiac end compared with the intermittent ejection through the pyloric stoma may so affect a particular part of the jejunal mucosa that ulceration occurs, as the acidity is less likely to be immediately neutralised.

With regard to the effect of gastro-enterostomy on the motility of the stomach, as to whether it is a "drainage" operation, Mr. Paterson's observations,[17] to my mind, prove nothing. The point is, What part of the stomach does it drain"? A careful operator, like Mr. Paterson, is unlikely to make the opening in the cardiac enlargement and there- re in his cases food will *not* pass *at once* into the jejunum. will, as he shows, have practically the same nutritive lue. I venture to say, however, that his reasoning with gard to these facts is wrong. They do not necessarily pport his contention that gastro-enterostomy is not a ainage operation. It must procure drainage or, rather, t as a short circuit or a "safety valve" before it can bring out the good effects which it does. In Cannon's observa- ns on cats, which are so frequently referred to, in the eater number of cases the opening was evidently a small e, and food preferred to pass through the pylorus. In the y case in which the opening was without doubt a large h, food passed more readily through this opening. This is at should be aimed at in the human subject. I point out t these experiments were carried out in presumably mal animals and therefore the conditions are not com- able to those demanding gastro-enterostomy in the human ient, in whom pyloric spasm or actual stenosis compels d to pass through the new opening at all events until sm has been relieved by more normal reaction of the tric contents. There need be necessarily no marked ct on the emptying power of the cardiac portion when opening in the operation of gastro-enterostomy is made the pyloric portion. (The nutritive value of the food uld then be as good as in any other individual. It may better so far as the patient is concerned than before ration.) In the majority of operations the cardiac portion ertainly not drained, and it is into this portion that the e is passed in order to draw off the gastric contents after st meal. Mr. Paterson's findings appear to me to form rong argument in favour of the "two compartment" ry I have put forward.

esults obtained with the "salol test" uphold my con- ions. In repeated observations with this test, when the ation is done as I have indicated, *there is practically eparture from the normal in the results obtained*. These arks apply as well to cases of pyloric spasm (with ulcera- in the neighbourhood) as to cases of cicatricial stenosis. astro-enterostomy meant drainage of a "one compart- t" organ, then the salol ought to reach the small stine and hence appear in the urine at a much earlier d, especially in cases of actual pyloric stenosis.

. conclusion, I should like to say that recently I have endeavoured to practise what I have been preaching, and the results are, to my mind, all that could be desired. Since the no-loop method was introduced the results of this operation have vastly improved, i.e., practically since the opening has *not* been made in the cardiac portion. Before the introduction of this method absence of evil results, if the Y operation was not done, was hailed with satisfaction. Now it is looked for almost with certainty. I venture to assert that with attention to the points I have mentioned fortuitous openings in the cardiac portion will be avoided and the results will be more satisfactory still.

To sum up. (1) The cardiac and pyloric portions of the stomach are distinct in development, structure, function, and pathology. (2) During the early stage of gastric digestion the pyloric portion is normally empty and tonically contracted. When food has attained a proper chemical reaction in the cardiac enlargement it passes into the pyloric portion. (3) Bearing this in mind, care should be taken in performing gastro-enterostomy to make the opening in the stomach wall within the pyloric portion, as near the pylorus as possible. This will, then, if the stomach has not irremediably lost its muscular power, provide against an "uncontrolled escape of the acid gastric contents," which is asserted by Dr. H. C. Cameron[18] to occur in cases of gastro-enterostomy. If pyloric spasm be present the stoma will act as a safety-valve and remove the spasm. If pyloric stenosis exists the natural condition of things will be most nearly approached and the "regulating action" (Pawlow) of the pylorus, so necessary to perfect digestion, be most nearly approximated.

NIGHT BLINDNESS.[1]

BY J. HERBERT PARSONS, D.SC. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE HOSPITAL; ASSISTANT OPHTHALMIC SURGEON TO UNIVERSITY COLLEGE HOSPITAL; OPHTHALMIC SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON, W.C.

WHEN a patient comes to us complaining of inability to see in the dusk or in foggy weather we at once think of the disease commonly known as retinitis pigmentosa. If we were practising in India we should be much more familiar with patients complaining of this symptom and should be less likely to attach the same importance to it. There have recently been several excellent examples of retinitis pigmentosa in my clinic and you have had the opportunity of making yourselves fully acquainted with its peculiarities. It is only necessary for me, therefore, to review very briefly its principal features. The routine examination of the patient shows that there is comparatively little disturbance of central vision, though there are exceptions to this rule. Examination of the fundus shows in the early stages in young patients a zone of characteristic retinal pigmentation in the neighbourhood of the equator; both peripheral and central to this zone the retina looks almost or quite normal. I need not dwell upon the striking characters of the pigmentation—the spots shaped like bone corpuscles and the aggregations along the perivascular sheaths of the retinal vessels. At this stage we may expect to find a ring scotoma on examination of the field of vision. My senior clinical assistant, Mr. M. L. Hepburn, has recently devoted much attention to the nature of this scotoma and has shown amongst other points that it is seldom complete, but is dotted over with areas in which vision is only partially lost. Probably these areas are closely related to the distribution of the vessels, but for an exhaustive discussion of the subject I must refer you to Mr. Hepburn's admirable paper in the last number of the Hospital Reports. At a later stage the zone of pigmentation has extended both peripherally and centrally, and the field now shows uniform contraction, the peripheral area of vision having become abolished. The progress is usually very slow and central vision is seldom lost by the extension of the choroido-retinal disease to the macular area. Before this occurs a posterior cortical opacity appears in the lens, which, however, has much the same effect upon the visual acuity. This so-called idiopathic retinitis pigmentosa is a progressive form of chronic night blindness. It is an obscure disease in which heredity and the consanguinity good apparatus it will be found that the test shadows can easily be obtained in ordinary cases.

[18] Brit. Med. Jour., Jan. 18th, 1908.

[1] From a clinical lecture delivered at the Royal London (Moorfields) Ophthalmic Hospital on Feb. 1st, 1908.

In the same way the method can be used to test the effects on the photographic plate. This is of special value when, owing to the stoutness of the patient, the shadows cannot be shown on the screen. The plate is much more sensitive than the human eye to x ray impressions and under certain conditions its results are more accurate. A radiogram is taken with the test placed between the tube and the patient in the same manner as in the screen examination. If the test shadows show on the plate another radiogram taken under exactly the same conditions, but without the test, will show any calculus in the patient. The tube, however, varies considerably during even one ordinary exposure and a quite accurate result can only be obtained by taking a radiogram to include both sides of the patient and with the test on the side opposite to that under examination. This is especially useful in renal cases. When an image of the test is shown through one kidney it can be used as before to compare any opacities in the other renal area or to prove that if there is no opacity there is no stone.

A convenient plan, when the test shadows cannot be seen with the calculi between the tube and the patient, is to place the test immediately under the screen. The rays now pass first through the patient and then the calculi and *therefore an image of the test will not prove that a calculus* in the patient must also be seen. But if the rays can show the test they will be found sufficient to give a definite image of any calculus in the patient on a radiogram.

In a comparatively small number of cases, those of very stout patients, it will be found impossible to show the test calculi by any method. In these the x rays are valueless and the diagnosis must be made from the physical signs and clinical symptoms. But it is of great practical importance to differentiate these patients from the large number in which it can be proved that no stone is present and thus to decide whether or no an exploratory operation is justifiable. A negative result with the ordinary radiographic methods may mean either that no stone is present or that the rays have failed to show it, and unless the value of the rays employed is known the diagnosis is of no practical use. Even in a simple case a good photograph showing all the so-called typical diagnostic signs may, and sometimes does, fail to show a stone and, from its very photographic excellence, be worse than useless as a radiogram.

The method gives the best results by the combined use of the screen and plate. On the former the presence and position of any opacity, its size, and relative density are noted, and especially when there is any movement on respiration, whether it is synchronous with that of the kidney shadow or of the intestines. The information obtained in this way can then be verified by a radiogram and in doubtful cases by re-examining any suspicious areas. Calculi placed outside the body have previously been demonstrated and a useful modification of the method described has been employed in searching for foreign bodies in the œsophagus, stomach, &c. In cases of urinary calculi it is in the systematic use of the method that its value lies, and in providing a standard of comparison and a practical means of estimating the actual diagnostic value of the x ray results.

Welbeck-street, W.

"DAMMED CIRCULATION" AND "INTERRUPTED CIRCULATION."

A NOTE IN NOMENCLATURE

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL; SENIOR PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN.

THE expression, "Bier's method," is a sufficient description for the initiated, but for others it offers no suggestion as to what is meant. In the past this same method failed to develop and to spread so long as it stood without a name of its own, and identified in literature merely as "v. Dumreicher's method."[1] At present there is no lack of names; the only inconvenience is their variety and, according to Dr. Alfred R. Allen,[2] their inaptness. "Passive congestion," "passive hyperæmia," "stasis hyperæmia" are all unsatisfactory for him and, with perhaps too little faith in our own language, he proposes to look elsewhere for the word. Of course, in our complicated clinical craft there is much in a name. Names should be accurate, but also if possible telling in suggestions and in reminders; and it is precisely because agreeing with the practical purpose entertained by Dr. Allen that one rather shrinks from the formidable Teutonism "Stauungs-hyperämie" which he advocates as an improvement for our daily use. *If one may be allowed to question two of his* statements, we have *not* had to search in vain "for a concise descriptive term in our own tongue"; and it is hardly in the phrase "Stauungs-hyperämie" that we shall find a complete "mental picture of the mechanics of the method": except for German ears it could only convey *ignotum per ignotius*.

As a fact, this is only an imperfect translation of our own original descriptive expression "dammed circulation," first used some 30 years ago by Hugh Owen Thomas, the pioneer of the method in this country.[3] The English name is more strictly inclusive than the German, for it implies the manœuvre and covers the entire field of its operations, arteries, veins, capillaries, and, not least important, *plasma and lymphatics;* whilst "passive hyperæmia" connotes only *the intravascular condition. As the vast extension* of the benefits of the method is entirely due to Bier his name deserves to be linked with the term, and no further excuse is needed for the suggestion which is now submitted in favour of the adoption in this country of the expression, "Bier's method of dammed circulation," which may ultimately be found a convenience in others. But there is another reason, of clinical utility. Since the Esmarchian era in surgery, and since Harvey Cushing's happy use of the tourniquet in Raynaud's disease, "interrupted circulation" has been shown to be an important therapeutic agent in clinical medicine and surgery.[4] Whilst this is physiologically the reverse of Bier's method, both are *vessel-compressing* methods, and they need to be strictly distinguished by their respective names. It would probably *be difficult to find less ambiguous terms* than "interrupted circulation" on the one hand and "dammed circulation" on the other. Indeed, the names *proposed* might almost be said to be mutually explanatory for the two methods.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Coxa Valga.

A MEETING of this section was held on Feb. 11th, Mr. J. WARRINGTON HAWARD being in the chair.

Mr. A. H. TUBBY read a paper on Coxa Valga. He said that coxa valga was an opening out of the angle made by the head and neck of the femur with the shaft, in some cases to such a degree that the upper extremity of the femur and the shaft appeared to be almost in a straight line. It was the *opposite* condition to coxa vara, in which the head and neck of the femur sank down until they were placed at a right angle, or even less, with the shaft. A considerable degree of terminology and mensuration had grown up in connexion with the *deformities* of the upper end of the femur. The most important was the angle of inclination, other*wise called the angle of* depression, the cervical angle, or the angle of the femur. It was estimated by drawing one line through the long axis of the shaft of the femur, and a second line through the long axis of the head and neck. The angle formed on the inner side of the point of intersection was the angle of inclination. Other lines and angles were *Hoffa's* line, Alsberg's angle, Alsberg's triangle, and the angle of declination. A list of museum have begun to leak. In the latter case its size would be in part due to extravasated blood. It is also of some interest to notice that the femoral artery could be traced over the swelling for an inch or more both above and below its centre. It therefore seemed probable that we had to deal with a sacculated aneurysm situated on the outer side of the femoral artery in Hunter's canal. In this position it would be able to cause compression of the vein against the bone and œdema of the leg and foot. This œdema of the left leg was the first indication of anything abnormal. As the swelling in the thigh increased in size and became more obvious it was again carefully examined and found to pulsate. The central part of the pulsating swelling at the end of April was quite soft and appeared to be approaching the surface. There was evening pyrexia rising to 100°. His arteries were thick and tortuous and the heart action was rather feeble. An operation therefore at the age of 78 years caused us some anxiety. On the other hand, the pulse could be felt quite plainly at the ankle, and it was hoped that ligature of the femoral artery just above the aneurysm at the apex of Scarpa's triangle would be sufficient to arrest its progress. The aneurysm with its surrounding swelling now occupied the middle of the left thigh just reaching to the apex of Scarpa's triangle.

[4] Interrupted Circulation as a Therapeutic Agent: Illustrated in Two Cases of Rheumatoid Arthritis, THE LANCET, August 13th, 1904, p. 442; also Transactions of the *Royal* Medical and Chirurgical Society, vol. lxxxix., 1906.

On May 2nd, four months after the onset of the pneumonia, the femoral artery was ligatured just above the margin of the swelling. Dr. Bevan gave the anæsthetic and had a good deal of anxiety over his patient, who showed signs of cardiac distress during the operation. Mr. C. A. R. Nitch gave much valuable help and assistance. The sheath was unusually adherent to the artery which had very thick walls and was rather tortuous in its course. Two double strands of floss silk, making four ligatures in all, were passed beneath the artery and separately tied without dividing the coats. Pulsation in the aneurysm and at the ankle was arrested by the ligature. The pulsation never returned at the ankle, but in the aneurysm it was occasionally detected on careful examination during the next fortnight. The foot remained warm and of good colour throughout. The temperature began slowly to rise after the sixth day from the date of the operation, when the sutures were removed. From May 10th to 22nd there was pyrexia (102°) every evening, although the wound appeared to be perfectly sound and to have healed by first intention. The aneurysm, on the other hand, whilst the temperature was rising, steadily increased in size, and finally gave one the impression of being an abscess. It roughly extended from the inner side of the knee to the buttock; the most prominent part was situated about the centre of the inner side of the thigh. As it was still doubtful whether the swelling was due to extravasated blood or to suppuration the blood was examined and the result strongly suggested suppuration.

On May 23rd an anæsthetic was given by Dr. Bevan and with Mr. Nitch's assistance an incision was cautiously made through the centre of the swelling. What appeared to be blood escaped in large quantities. Having preserved some of this fluid in sterile tubes the cavity was fully explored and found to be very large, extending far beyond the limits of the original aneurysm. As it did not appear now that there was any direct arterial communication with this cavity and that the fluid was old softened blood-clot, the wound was left open without either a drainage-tube or gauze plug being inserted. The dressing had to be frequently renewed as there was a constant discharge of a large amount of blood-stained fluid. At each dressing this fluid could be squeezed out of the wound and on careful measurement amounted in 24 hours from five to eight ounces. The temperature during this time dropped from 102° to 101°. As no further diminution of the discharge or fall in the temperature took place an anæsthetic was given on June 11th and the wound was freely enlarged. Two counter openings were also made, one towards the knee and the other at the back of the thigh towards the gluteal fold. A drainage-tube was introduced into each opening. The highest temperature in the 24 hours quickly dropped to 100°, and by June 20th it was only 99°. The whole thigh also began to diminish in size, the œdema of the foot disappeared, and the patient improved rapidly in general condition. By the end of June the discharge was of slight amount and the highest temperature was always below 99°. Our anxiety was thus at an end. On July 14th, when the wounds were nearly healed, the temperature rose slightly and he complained of pain in the left groin. The femoral artery, which had been previously pulsating up to the seat of the ligature, could not be recognised below Poupart's ligament, and œdema of the leg and foot was again apparent. Thrombosis of the artery from the seat of the ligature up to Poupart's ligament had obviously taken place. In about a week's time the pain had gone, the temperature was 99°, and the artery could be felt as a solid cord up to and beneath Poupart's ligament. The œdema of the foot, however, remained. The last drainage-tube was removed on July 21st. Early in August he was able to leave London for Mr. H. C. Crouch's home at Ascot. The wounds were practically healed and the œdema had almost disappeared. There was slight pitting on pressure over the shin but none on the dorsum of the foot. The artery in Scarpa's triangle was a painless solid cord. Once again, at the end of August, he had an attack of inflammation in the left groin. Pain, tenderness, and swelling round the femoral artery with a slight rise of temperature gave the same indications as before, and naturally aroused a suspicion of further extension of the thrombosis. But as there was no œdema of the foot it was hoped that the inflammation was confined to the part previously affected, and that there was no extension of the thrombosis to the external iliac artery. Within a week the attack had disappeared, leaving the artery as it was before.

Pathological report.—On May 21st an examination of the blood was made with a view to determine, if possible, whether suppuration had occurred in the aneurysmal sac. The result was as follows: leucocytes, 22,740 per cubic millimetre. A differential count of 500 cells was made, of which 86 per cent. were polymorphonuclear neutrophiles and 1·25 per cent. the Ehrlich type of neutrophilic myelocytes.

A bacteriological examination of the contents of the sac of the aneurysm was obtained on May 24th. Film-preparations were made from the coagulated blood which had been received in sterile tubes. The cells were chiefly microphages, the remainder macrophages. Diplococci were numerous; they were Gram-positive and the majority were extracellular. A pure culture of the diplococcus was obtained from the coagulated blood. This organism was found to be the pneumococcus. It gave the reactions which are most commonly obtained in the artificial media employed by Andrewes and Horder for the differentiation of the streptococci. On May 27th a second bacteriological examination was made. The contents of the tubes consisted of blood-stained pus, in which there were large numbers of both extra- and intra-cellular Gram-positive diplococci. A pure culture was obtained but on this occasion the organism was extremely difficult to cultivate and died out very rapidly. On June 4th a third examination was made. Film preparations of the pus showed numerous Gram-positive diplococci. A few bacilli were also present. The cultivation experiments were found to be sterile.

This case is of interest, even if it were regarded merely as an example of suppuration in an aneurysm without reference to the intrinsic cause, but owing to the fact that the pneumococcus was obtained in pure culture from the contents of the aneurysmal sac, and that the patient had only recovered from acute pneumonia quite recently, it may be considered as a case of exceptional rarity in surgical pathology. The first question which naturally arises is whether an aneurysm was present previously to the attack of pneumonia. Dr. Bevan tells us that he is unable to answer this question. If we allow that a small aneurysm of the femoral artery was present previously to the acute illness, then probably either a clot in the interior of the sac became infected by the pneumococcus, or an atheromatous patch in the wall of the aneurysm became the seat of an acute infection by this organism, with subsequent thrombosis. It has already been stated that the contents of the aneurysm, when first received in the laboratory, consisted of coagulated blood, which had undergone acute inflammation, while a few days later true suppuration had occurred. If we allow for the sake of argument that there was no aneurysm previously to the acute pneumonia, then we have to decide whether the patient developed an acute embolic aneurysm as a result of infective endocarditis, or whether the atheromatous condition of his arteries led to direct pneumococcal infection of the wall of the femoral artery.

It is well known that even the most severe forms of infective endocarditis may not be diagnosed during life, but even allowing for this fact there was no reason to suspect in the case under discussion that acute endocarditis had occurred. Dr. Turney, who was called in to consultation subject of locomotor ataxy and there was no indication that he suffered from infantile paralysis. The case illustrated the fact that *dislocation of the patella* need not necessarily interfere much with the utility of the knee and suggested that an injury to a joint in early life might determine the onset of osteo-arthritis in the joint so affected. The skiagrams of the case of old fracture of the humerus were from a patient, aged 34 years. *21 years ago, when the patient* was aged 13 years, he injured his right elbow; he said it was *dislocated*, but he did not know whether it was fractured. Three and a half years ago a small, painful swelling appeared near the elbow, which was treated in hospital. *Soon afterwards* a swelling appeared on the inner side of the back of the forearm, two inches *below the internal condyle*, which increased in size during the last year till it reached that of a walnut. It proved to be a "ganglion" with a thin wall, the pedicle of which extended up towards the joint along the internal intermuscular septum. The clear, jelly-like contents were evacuated and the pedicle was cut short. The *wound healed by first intention*. The skiagram showed an old fracture of the internal condyle and irregular masses of bone attached to both the upper ends of the ulna and the radius. The movements of the joint were almost perfect. The case illustrated the good result which might *sometimes be obtained after fracture* of the lower end of the humerus. It also suggested that an injury to a joint in youth might determine the onset of osteo-arthritis later in life. There was at present, however, no creaking in the joint. No signs of osteo-arthritis had been discovered in other joints.—After Mr. T. H. OPENSHAW and Dr. SEYMOUR TAYLOR had spoken, Dr. F. J. POYNTON remarked that osteo-arthritis could be produced experimentally in an uninjured joint—an *injury might diminish the resisting power* of a joint to some infection.—Dr. GARROD concurred with the view expressed *in regard to lowered resistance.*

Dr. SEYMOUR TAYLOR showed a case of Ruptured Aortic Valve. The patient, a man, aged *34* years, who had worked with lead for nearly two years, complained of tightness across the chest, a choking sensation on exertion, and a buzzing noise in the chest, which he heard best when lying down. These symptoms supervened suddenly after the strain of lifting a heavy weight. He denied having had syphilis or acute rheumatism but had twice suffered from lead colic. He had a typical blue line at the edge of the gums. On palpation over the cardiac region a diastolic thrill was felt, most intense over the second and third spaces on each side. On auscultation a loud *murmur* was heard, loudest over the aortic area, diastolic in period, and musical in tone. The musical note corresponded to about B below the staff. That point was of some interest, as a similar observation was made in a previous case which he had shown before the Clinical Society (*Transactions*, vol. xxxvi.). The murmur was heard all over the chest and even over the upper *thirds* of the humeri. The condition of the valve was probably one of perforation of one cusp rather than of detachment or true *rupture*. That diagnosis was made *on* the following grounds, viz.: (1) the sudden onset *of urgent* symptoms after a strain, pointing to valve injury; (2) the musical diastolic murmur; and (3) a marked diastolic thrill. If a cusp were torn from its attachments one would expect to hear harsh noises, and also to feel a thrill, not *only during diastole*, but also during systole.—Sir J. F. H. BROADBENT narrated a case in which rupture of an aortic valve was *diagnosed*, but it was found at the necropsy to be one of acute aortitis.—Dr. POYNTON observed that it was possible *for* an *aortic* valve to be ruptured without the patient experiencing pain, perhaps *only* complaining of a little discomfort.—*Dr.* THEODORE WILLIAMS said a ruptured aortic valve might act as a valve below the level of the other two valves.—After Dr. PARKES WEBER had spoken *Dr.* SEYMOUR TAYLOR replied.

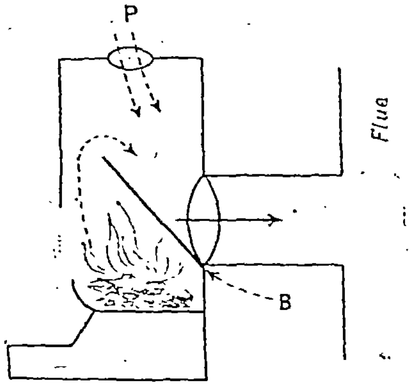
Dr. ARTHUR LATHAM showed a case of Caseating Pulmonary Tuberculosis treated *with Tuberculin* (T.R.) and Horse Serum, both given by the mouth. The patient was a man, aged 26 years, who on June 3rd, 1907, was seized with acute pneumonic tuberculosis of the left lower lobe. He had continuous fever till the beginning of October when he sought advice at Brompton Hospital for Consumption. He was admitted to St. George's Hospital on Oct. 8th and kept in bed for one month without reduction of the fever and without any evidence of improvement. On Nov. 6th 10 cubic centimetres of horse serum with $\frac{1}{1000}$th *mgrm.* tuberculin were administered by the mouth, followed by a drop in the temperature to normal for two days. On Nov. 9th the *temperature again rose to* 101° F. A further dose of serum and tuberculin was given on Nov. 11th. On the 12th the temperature was subnormal. On the 13th the temperature again rose. On the 20th and 21st serum and tuberculin were again administered with immediate effect. The temperature *remained normal* till Dec. 12th *when* the patient was allowed up; that was followed by immediate auto-inoculation and *fever*. A further administration of serum and tuberculin again reduced the temperature, which remained *near the normal* till Jan. 3rd. On that date three doses of serum (10 cubic centimetres) and tuberculin $\frac{1}{1000}$th *mgrm.* were *administered, with the* result of a summation of negative phase and increased temperature. That proved a temporary affair. For the last month the temperature had been normal or subnormal. The patient was up and about. The weight had increased 17 pounds and the sputum diminished from 6 ounces to ½ ounce. The physical signs in the left lower lobe were those of a dry cavity.—Dr. PARKES WEBER said the case might have some bearing on the feeding of consumptive patients with tuberculous meat. —Dr. THEODORE WILLIAMS thought it was important to examine the expectoration for traces of lung tissue.—Dr. LATHAM, in reply, said that immunisation by tuberculous meat was a possibility and experiments in connexion with that point were being carried out at the Pasteur Institute.

Dr. PARKES WEBER showed a case of Spurious (?) Acromegaly. The patient was a woman, aged 46 years. The case was shown because of its remarkable resemblance at first sight to acromegaly. The patient was married, rather corpulent, and very anæmic. Her *face* and head, with the large lower jaw, prominent chin, and big nose, could be used as a model for an illustration of acromegaly. She had thick, fleshy hands and thick fingers, but she had no ocular symptoms of acromegaly and her occasional headaches *and shortness of breath seemed to be connected* with her anæmia, which in its turn might be accounted for by frequent hæmorrhoidal bleeding from which she *had suffered during* the last six or seven years. There was no amenorrhœa, as there was in many genuine cases of *acromegaly. Moreover*, there was no evidence of any progressive change having occurred in the shape or size of the *hands, feet, face*, skull, or other bones of the body since she *ceased* growing at the ordinary age. An old photograph (the only *one obtainable* for comparison) which was taken three or *four years ago* showed her face looking just as it did now. She had had six children, all healthy, and at least one of the daughters somewhat resembles the patient *in the shape of* her chin. The case had probably been more than once accepted as one of genuine acromegaly.

Mr. SPENCER showed a case of Lateral Curvature rapidly developing in a boy, aged three *years, who* was an inmate of a Poor-law school, and was all at once noticed to have a marked lateral curvature, the only *previous* observation being that he *seemed* a *little* anæmic. He had a marked left thoracic and lumbar scoliosis and walked with *lordosis*; both of the curvatures *disappeared when* he was suspended by the arms. The muscles of the left side of *the* spine appeared unduly weak, the abdomen was irregularly protuberant, but there was no definite hernia, either inguinal or ventral. The hæmoglobin was 74 per cent. Beyond that the examination had *discovered* nothing distinctly abnormal; the reflexes were normal, the muscles of the spine reacted to faradism and galvanism; no *muscles were* absent.

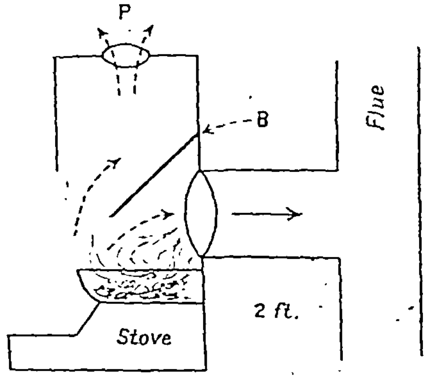
Mr. R. P. ROWLANDS showed a case of Excision of the Body of the Scapula. The patient was a man, aged 35 *years*, from whom the whole of the body of the left scapula had been excised for enchondroma 15 months ago. *It* was *possible*, and deemed advisable, to save the coracoid process with its important muscles and ligaments, the glenoid *cavity* with *the capsular ligament* of the shoulder-joint, and the acromion process with the attachments of *the* deltoid and trapezius to it. The patient showed that both the disability and the deformity following that procedure were much less than after *complete* excision of the shoulder-blade. The man had been *able to do* his work as a painter's labourer from two months after the operation. Extreme abduction was the *only* movement that was imperfect. Radiograms were exhibited to show the comparative effects *of the operation* adopted in the patient and of complete excision of the scapula for extensive sarcoma by Mr. L. A. Dunn, *who had* kindly allowed Mr. Rowlands to make use of his *case*. Photographs were also exhibited which showed the *differences* of function and degree of deformity in the two cases. Rotation of the shoulder-joint room is oblong, 18 feet × 12 feet × 11 feet high, and has a gabled roof; there are two windows on one side and a curtained door at the other. Above the door is a primitive ventilator formed by a wooden flap which is opened and closed from outside. This I am told if left open the patients close. It appears that the night of Jan. 20th was cold and heavy and the patients closed the ventilator and windows. Most probably when the stove burnt low the draught was insufficient to force its way into the long cold column of air in the brick flue and found an easy exit past the flame baffler into the room.

FIG. 1.



B, Flame baffler as it should be set. P, Perforated cap on the top of the stove.

FIG. 2.



B, Flame baffler as it was set on the occasion of the accident.

The case was full of interest especially as regards the different times of the deaths of the patients; the youngest evidently succumbed first and the other some time later, while the eldest alone survived. The insidious nature of the poison is apparent; all the patients appear to have slept away undisturbed, while the surviving one now has no recollection of anything unusual having happened. The definite proof by the spectroscope of the cause of death is also satisfactory; and the danger arising from the imperfect fixing of what are supposed to be innocuous stoves is an important point which cannot be passed over lightly.

Leighton Buzzard.

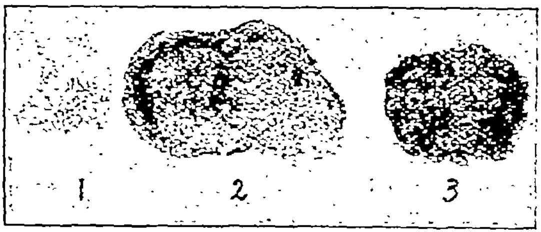
ROYAL UNITED HOSPITAL, BATH.—The annual meeting of the subscribers to this hospital was held on Jan. 29th. Mr. S. Bush, the ex-mayor, was awarded a special vote of thanks for his successful efforts in raising a fund of £6214 to free the hospital from debt. It was stated that the legacy from the late Dr. J. Bennett would result in an additional income of £700 per annum. The financial statement showed that there was a deficit of £654 on the working of 1907, and the committee decided to pay this off from capital so as to commence 1908 absolutely free from debt. The medical report was satisfactory.

A METHOD OF X RAY EXAMINATION IN CASES OF URINARY CALCULUS.

BY C. J. MORTON, M.D. EDIN.,
SURGICAL RADIOGRAPHER TO GUY'S HOSPITAL.

IN the examination of cases of suspected urinary calculus with the present x ray methods the results are not always trustworthy. While there is this uncertainty more reliance must be placed on the clinical symptoms and as these are frequently misleading accurate diagnosis is impossible and many cases are left unrelieved or are operated on unnecessarily. The chief reason for this appears to be that there is no satisfactory way of testing the efficacy of the rays and of estimating whether they are in the proper quantity and of the requisite penetrating quality to suit the particular case.

I have recently adopted a simple method by which it is possible to obtain not only more trustworthy information when stone is present, but also in most of the negative cases to demonstrate definitely that no stone can be present. It consists in the use of a set of calculi of known composition and size as a means of testing the actual effects of the rays while they are passing through the patient. These test calculi are placed between the focus tube and the patient, so that the rays pass first through the calculi and then through the part of the patient to be examined. If the rays are of sufficient strength shadows of the individual calculi will appear on the fluorescent screen and be readily recognised. If no shadows can be seen it means that the rays are inadequate and they must be modified in quantity or in penetrating quality to suit the individual case. The figure shows a radiogram of the calculi employed taken directly, not through the patient's body. Sections of three stones are mounted in a wooden handle with a metal end. Analysis of the remaining portions showed that No. 1, next the metal end, is composed of pure uric acid. The radiogram, however, shows that there are also some faint traces of more opaque matter, probably phosphates. No. 2, in the middle, is a fusible calculus of mixed phosphates, and No. 3 is a mixed stone, with a nucleus of urate of ammonium, a layer of oxalate of lime, and a coating of triple phosphates. Their relative size and density are shown in the radiogram. The oxalate stone is $\frac{3}{16}$ths of an inch and the uric acid and phosphate each $\frac{1}{4}$ of an inch in thickness. Discs of metal of corresponding density would be equally serviceable and much more easily obtained. In using this as a test the patient is placed on a couch and a focus tube fitted with a small diaphragm is moved about underneath the couch so that all the suspected area can be searched by the central rays. The examiner's eyes must be made sensitive to x ray impressions by resting for ten minutes in the dark or for from 15 to 20 minutes in a very subdued diffused light. A handle of about 12 inches in length is useful to get the stones into position and also to move them about, as they are then much more easily detected on the screen than when they are stationary.



When the shadows of the test have been obtained they are used as a standard with which any opacities in the patient can be compared and a more accurate opinion formed of their size, density, and nature. But perhaps the chief clinical value of the method is that it provides a means of deciding absolutely on the absence of stone. It is known that the nearer an object is to the screen the clearer and more defined is its shadow. If, therefore, the test calculi can be seen it follows that the shadow of any calculus of equal density lying in the patient and therefore nearer to the screen will also be seen. If no such shadow is visible no calculus can be present. With a suitable focus tube and fluid escaped and aspirated the rest with a lacrymal syringe. He then perforated the retina above and below. In the middle of January the field was quite full.

Mr. HORSFORD showed a case of Buphthalmia with Malformation of the Iris, and the causation of the condition was discussed.

Mr. J. F. CUNNINGHAM showed an Orbital Case for Diagnosis. It was thought to be apical periostitis, or caries of the apex of the orbit, or an optic nerve tumour.

Mr. J. H. FISHER showed a patient with Microphthalmia and a case of Fundus Changes resulting from injury at birth. The second of these patients was born with great difficulty and there was a huge hæmatoma of the left frontal region, and soft tissues in the right temple and orbit were much damaged and lacerated by forceps. Possibly the optic nerve was damaged and there was hæmorrhage from the lacerated vessels into the hyaloid canal, the clot forming the basis for the connective tissue organisation. He did not think there was any shrinking of the globe.

Mr. P. C. BARDSLEY showed a case of Retinitis Proliferans. A large bundle of connective tissue came forward into the vitreous. He regarded it as congenital, as there were a large detachment of the retina and only a very small field. There was no history of injury, either at birth or since, but the eye had been defective as long as the parents could remember.

Mr. C. WRAY showed a case of Follicular Conjunctivitis which he considered to be perfectly curable. It was contagious, and among 1400 children in the Croydon schools there were 12 cases of the condition.

Mr. J. H. PARSONS showed a patient the subject of a condition which he thought was probably Metastatic Neuro-retinitis. A woman had a glistening mass of exudate over the left disc with considerable swelling and some hæmorrhages on the disc. Then she suddenly lost the sight of that eye. The exudate diminished, leaving a glistening white star resembling that seen in albuminuric retinitis. She had no albuminuria.

SOCIETY OF ANÆSTHETISTS.

The Status Lymphaticus in Relation to General Anæsthesia.

A MEETING of this society was held on Feb. 7th, Dr. R. J. PROBYN-WILLIAMS, the President, being in the chair.

The discussion on Status Lymphaticus adjourned from the last meeting was resumed by Mr. R. GILL who congratulated Dr. W. G. McCardie on his paper and directed his remarks chiefly to two features which Dr. McCardie had mentioned as existing in the status lymphaticus—viz., (1) some nasopharyngeal obstruction, and (2) anæmia. These two factors were very intimately connected with the action of chloroform. Patients with nasal obstruction exhibited a long induction period and anæmic people required very little chloroform. A combination of these conditions produced a patient to whom it was difficult and dangerous to give chloroform. And this combination occurred in people who were not subjects of status lymphaticus. It was difficult to see that there could be any relation between the enlargement of such organs as the spleen, liver, glands, &c., and susceptibility to chloroform, so he concluded that there was not sufficient evidence that the status lymphaticus in itself was the cause of these deaths under chloroform.

Dr. DUDLEY W. BUXTON could not agree that Dr. McCardie's conclusions followed his premisses. He could not help feeling that the status lymphaticus which had been discovered in many cases of deaths under chloroform was coincidental and not causal. Dr. McCardie had used the word "idiosyncrasy," but he (Dr. Buxton) did not believe in idiosyncrasy to chloroform. Everybody had his dose for chloroform and it was the duty of the anæsthetist to discover it. There were two schools as to the cause of death in these cases: one said they were cases of respiratory obstruction, the other called them cases of syncope. The pathological conditions in status lymphaticus would produce more or less respiratory obstruction, and if expiration in particular were obstructed the chloroform would become locked up in the chest and absorption and poisoning would occur, especially as the myocardium in status lymphaticus was feeble to start with and the dilatation from chloroform might not be recovered from. As to these deaths being due to syncope, Embley and Martin had shown that a certain percentage of chloroform in the circulation would prevent vagal inhibition, but that with a larger percentage vagal inhibition would not be prevented and would not be recovered from. If a given percentage of chloroform enabled a heart to escape from vagal inhibition in a normal patient might not a patient the subject of status lymphaticus with the same percentage of chloroform not escape vagal inhibition and not recover from it? Patients with status lymphaticus required less chloroform. Syncopes and asphyxias might be avoided by regulating the dose and only giving as much as was required. Some German authors referred to "thymus deaths" in adolescence, but these people did not die as suddenly as the ones under chloroform, they had glottic spasm, vomiting, &c., more like post-chloroform poisoning. The latter was probably due to lymphatic hyperplasia.

Dr. J. BLUMFELD disagreed with Dr. McCardie who doubted if death ever occurred from chloroform *per se*; many cases had been reported in which status lymphaticus was not present, and even in some of Dr. McCardie's own cases status lymphaticus was probably not present, especially some of the cases of goitre. Dr. Blumfeld also disagreed with Mr. Gill who seemed to doubt the existence of the status lymphaticus as a pathological entity; and finally he disagreed with Dr. Buxton in considering all these deaths as due to simple over-dosage, because cases had been reported in which corneal and movement reflexes were present when death occurred.

Dr. J. F. W. SILK regarded the enlargement of tonsils and adenoids in these cases as important factors in causing death. The signs and symptoms of status lymphaticus were so numerous and widely distributed that any case of death under chloroform might be dragged into the status lymphaticus net. He pleaded for a better definition of the condition and agreed with Dr. Buxton that they should, and usually did, avoid trouble by adjusting the dosage to the patient's requirements.

Dr. LL. POWELL asked if pathologists could say whether a persistent thymus was not occasionally found in people dying from some independent disease.

Dr. G. A. H. BARTON said that the status lymphaticus was a question for the pathologist. How could it be recognised? Might not a committee be formed to make blood counts of all patients anæsthetised to see if it were dangerous to give chloroform to people with lymphocytosis? Might not some deaths be due to too little and not too much anæsthetic? Dr. Barton did believe in idiosyncrasy to chloroform; he had seen idiosyncrasy to iodide, belladonna, and morphine, then why should it not occur to chloroform? But even if the physiologists were right that 2 per cent. of chloroform could not kill, he maintained that 2 per cent. would not always produce anæsthesia and that death might occur from other causes than the anæsthetic.

Dr. BUXTON apologised for getting up again and said that although he held no brief for the physiologists, yet it was possible clinically to obtain and maintain anæsthesia with 2 per cent. of chloroform.

The PRESIDENT said that the question whether status lymphaticus was a clinical entity or not must be left to the pathologists to determine. Until they could point to some more definite lesions it must be considered "not proven." As to Mr. Harvey Hilliard's case, he had invited criticisms and the President saw no reason why the patient should not have been given gas and ether.

Dr. MCCARDIE, in reply to Mr. Gill, said that in no case had obstructed breathing been reported. Anæmia would make the anæsthetist careful to equate the dose of chloroform to the patient's requirements, but he did not think these two factors sufficient to account for the sudden deaths. To Dr. Buxton he said he did believe in idiosyncrasy, and overdose was ruled out because so many cases occurred during light anæsthesia. To Dr. Blumfeld he explained that he did believe death from chloroform might occur apart from status lymphaticus. To Dr. Silk he declared his belief that status lymphaticus was a clinical entity and in one suspected case the x rays showed enlargement of the thymus. He agreed with the President that more pathological work was necessary and referred to the two cases mentioned by Mr. H. T. Wightman in which the status had been diagnosed. As to its mode of action in decreasing resistance to chloroform he did not know, but probably it was due to a form of lymphotoxæmia. He always gave ether when he suspected status lymphaticus.

specimens of coxa valga and an account of the cases hitherto described in literature were then read, and particular stress was laid upon two cases of Galeazzi of Milan, in which he had operated for the condition, and one by Nathaniel Allison. As to the causes of coxa valga, they were classified as follows: congenital, which were subdivided into those in conjunction with congenital dislocation of the hip, and those not associated with abnormalities elsewhere. Considerable stress must be laid upon the coexistence of coxa valga and congenital dislocation of the hip, and its importance was great. Coxa valga might not only be a determining factor in displacement of the head from movement at or after birth, but dislocation once having occurred the nearly vertical position of the neck and head of the femur induced great difficulties in satisfactory replacement. Mr. Tubby then cited three cases occurring in his own practice of congenital dislocation of the hip with coxa valga and showed x ray photographs and two cases. In one instance of dislocation of the left hip the angle of inclination was 169°. In a second case, with double dislocation, the angles of inclination were 172° and 164°, and in a third case, with dislocation of the left hip, the angle was 154°. A second cause was traction exerted by a pendent limb, such as occurred in extensive infantile paralysis of the lower extremity, and in those instances where amputation through the shaft of the femur had been required. A case was shown of infantile paralysis of the right leg, together with x ray photographs taken in three positions—namely, with the leg fully everted, fully inverted, and with the foot to the front. The angle of inclination was found to be respectively 204°, 128°, and 150°, thus showing 76° of difference in the various positions of the right limb, as compared with 27° in the left limb. Static conditions were also influential in causing coxa valga, particularly genu valgum and scoliosis, and a case in point was shown. A traumatic form had been frequently described, following injuries of the neck and shaft of the femur, and an instance which had come under Mr. Tubby's care was exhibited, in which, after mal-union of the middle of the shaft of the femur, the angle of inclination was found to be 152°. The deformity was also met with associated with rickets and processes of bony softening affecting the neck of the femur, such as osteomyelitis and tubercle. Some authors had also described an idiopathic form but the evidence as to the existence of that was not clear. Referring to the pathogenesis, Mr. Tubby said it could be shown that the normal shape and position of the head and neck of the femur depended upon the nice adjustment of certain forces—namely, weight-pressure, resistance of the bone, and muscular effort. If any one of those factors, or all of them, were varied in degree, altered in direction or destroyed, changes took place conformable with Wolff's law, and the head and neck of the femur assumed different positions and directions. The cardinal symptoms were abduction of one or both lower extremities, associated with external rotation and limitation of adduction. Pain and spasm were often experienced at the beginning of the affection and the gait in unilateral cases was limping, with the trunk inclined towards the affected side. In bilateral cases it was rolling and unsteady. The limb was frequently lengthened to as much as two or three centimetres and it was abducted and rotated out, whilst movements of adduction and internal rotation were limited. Trendelenburg's sign was reversed and the patient when standing on the affected limb inclined the body towards that side. Flattening over the great trochanter was often noticeable, and lumbar scoliosis, with its convexity towards the affected limb, was sometimes present. Very important evidence was obtained by skiagraphy and the fallacies in connexion with that were discussed. The diagnosis must be made from coxitis with abduction of the limb, from sacro-iliac disease, and from congenital dislocation not complicated with coxa valga. With reference to the treatment, various forms of operation had been performed—namely, cuneiform osteotomy of the neck, removal of a wedge of bone with its base inwards from the sub-trochanteric region, and linear osteotomy through the base of the neck. According to the conditions and surroundings of the patient one of the last two plans should be chosen.

After Mr. C. G. WATSON had made a few remarks, in the course of which he observed that he could not understand how the weight of the body could cause the condition described, Mr. TUBBY replied, and the meeting terminated with a demonstration by him of several patients.

CLINICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on Feb. 14th, Sir THOMAS BARLOW, the President, being in the chair.

Mr. J. P. ROUGHTON showed a case of Tumour of the Right Side of the Face. The patient was a boy, aged 11 years. The whole of the right side of the face, with the exception of the region below, and to the right of, the mouth, was occupied by a swelling of a doughy consistency, the upper eyelid especially being very swollen. This swelling crossed the middle line on the forehead and upper lip. There were many cords and knots distributed throughout the swelling, especially on the forehead, over the parotid, and in the cheek, and there was a distinct cord running immediately behind the facial artery over the ramus of the jaw. There was no pulsation. The swelling could not be diminished or displaced by pressure. There was no loss of sensation or movement except that the latter was very much impaired by the infiltration of the tissues and the muscles readily reacted to faradism. There was no leucocytosis. There was an enlarged gland under the sterno-mastoid. Eight years ago the mother noticed that the right eye looked smaller than the left and shortly afterwards the outer canthus began to swell, whence the swelling had gradually spread. The family history was good. He was at school till last December, when he left on account of pain in the upper eyelid which lasted about a fortnight and which was the only occasion on which he had had any pain.—Mr. R. J. GODLEE considered it was a case of plexiform neuroma and this was also the opinion of Dr. F. PARKES WEBER.—Mr. W. G. SPENCER and Mr. GODLEE agreed in recommending an exploratory operation and Dr. G. A. SUTHERLAND related the details of a similar case reported by him to the Clinical Society.

Dr. H. L. EASON demonstrated a case for Dr. HERBERT S. FRENCH of Tumour of the Mediastinum (? hydatid). The patient was a female, aged 42 years. She looked perfectly well and her only complaint was that she could not see properly with her left eye. For that she had seen Dr. Eason at Guy's Hospital. The cause of the defective vision was inability to accommodate. There was complete paralysis of the left cervical sympathetic nerve. That dated back for over two years. There was slight but decided ptosis of the left upper eyelid; the left pupil was continuously small; the patient could not blush upon the left side of her face and when she perspired the right side of the face sweated but the left did not. Further examination showed distinct fulness of the left external jugular vein and the veins over the upper part of the left chest in front were distinctly fuller than those over the corresponding part of the right side. Examination of the chest with the stethoscope showed complete absence of vesicular murmur and of voice sounds over the region where the upper two-thirds of the upper lobe of the left lung ought to be. The conclusion was that in the region of the left upper lobe there was a mass nearly as big as a good-sized orange, large enough to displace or to destroy the lung there, to extend back far enough to compress the cervical sympathetic nerve, and forward enough to compress the left innominate vein. The length of history and the general condition of the patient pointed to its not being malignant; there had been no improvement under treatment by mercurials and iodides, so that gumma seemed unlikely. The x rays showed a perfectly globular mass, not connected with the aorta (a point less obvious in the skiagrams than it was when the screen was used in different positions of the patient), and of a size precisely corresponding with the diagnosis made. Hydatid cyst was suggested as a possibility, chiefly on account of the perfectly globular character of the mass. The patient had no symptoms or signs of hydatid cyst elsewhere in the body.—This case was discussed by Dr. C. THEODORE WILLIAMS, Dr. A. E. GARROD, and Dr. CYRIL OGLE.

Mr. GODLEE showed a case of old-standing Dislocation of the Patella with Osteo-arthritis of the Knee in a man, aged 50 years, and Skiagrams of an old Fracture of the Humerus, with Osteo-arthritis of the Elbow. The patient with the dislocated patella was a labourer who said that his right knee had been out of shape since birth. He knew of no injury in early life. It did not cause him much, if any, inconvenience until he had a blow upon it six months ago, since which time his knee had been painful. On flexing the knee the patella slipped right over to the outer side of the joint. There was marked genu valgum and the signs of osteo-arthritis were unmistakable. The patient was not the rise in the calcium content of the blood, which seemed to show that in these cases inorganic salts or the calcium salts of the simpler organic acids were not capable of absorption. —The PRESIDENT and Dr. W. GORDON LITTLE also discussed the paper and Dr. BLAIR BELL replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

The Iliac Colon in Relation to Hernia.—Exhibition of Specimens.

A MEETING of this section was held on Jan. 24th, Professor A. FRASER being in the chair.

Dr. R. A. STONEY read a paper on the Anatomy of the Iliac Colon in Relation to Hernia, which we hope to publish at an early date.

Mr. ADRIAN STOKES exhibited a Fœtus showing Transposition of the Viscera and a Tricœlian Heart. It was obtained by Dr. Henry Jellett in 1896 and was described by him in THE LANCET of March 27th, 1897, p. 878. The fœtus was well formed and lived for a few minutes. Only the thoracic and abdominal cavities had then been opened, but in 1907 Mr. Stokes dissected the specimen and found other abnormalities. The heart had a single large ventricle and two auricles. The left or systemic auricle had no direct communication with the common ventricle, its blood passing through a large patent foramen ovale into the right or pulmonary auricle in order to reach the ventricle. This must be an extremely rare condition. There had been a few cases recorded in which the pulmonary auricle did not communicate with the ventricle, but none, so far as Mr. Stokes could find, in which the systemic auricle did not *do so*. The pulmonary artery also lay behind the aorta. Professor A. H. Young lately described a case of a tricœlian heart in a man aged about 37 years. In it the chambers of the heart were in their normal positions, but the aorta arose in front of the pulmonary artery. The condition of transposition of the viscera was rare. Only a few cases had been exhibited in Dublin, among which the best known was the one exhibited by Professor Fraser before the Academy of Medicine in 1894.

Professor FRASER exhibited—(1) the Hemispheres of an Encephalon, with well-marked Interruption of Both Central Sulci; and (2) a Duodenum of Unusual Form.

Professor E. P. M'LOUGHLIN exhibited—(1) a case of *Dorsal Origin of the Right Subclavian Artery, with associated Vascular Irregularities*; and (2) a case of *Unusual Position of the Large Intestine.*

SECTION OF MEDICINE.

Nephritis.

A meeting of this section was held on Jan. 31st, Dr. J. M. REDMOND, the President, being in the chair.

The PRESIDENT of the Academy (Dr. J. MAGEE FINNY) opened a discussion on the *Prognosis and Treatment of Nephritis*, limiting his remarks entirely to those inflammations included in the varieties—(*a*) acute nephritis due to toxic influences or exposure to cold; (*b*) subacute or chronic parenchymatous nephritis; and (*c*) chronic interstitial nephritis. He pointed out, however, that in every variety of nephritis there was more or less diffuse inflammation involving the glomeruli, the parenchyma, and the interstitial tissue. He then proceeded to discuss three principal features to be found in these cases: (1) albuminuria, (2) dropsy, and (3) the uræmic syndrome. He called attention to the harm which might be done to a patient's prospects in life by rejecting him for insurance or for admission to a post in the public services on account of albuminuria, pointing out that the condition might be due to adolescence or might be the result of temporary weakness of the heart. The treatment of albuminuria by medicine was as little encouraging as the use of hæmostatics in the hæmaturia of renal inflammation. The indications for treatment were to place the kidneys in physiological rest by cutting off all protein diet, such as meat, soups, beef extracts, and eggs; by feeding the patient at first with starvation diet when the inflammation was acute and the urine bloody and very scanty, and then allowing a very restricted diet of milk and starchy foods, with cream and sugar. The amount of liquid permissible at first must not exceed two pints in 24 hours, as the oliguria was due to renal inefficiency, and it was as harmful to try to produce diuresis by copious libations as by diuretic medicines. As soon, however, as the kidneys showed recovery by secreting more urine it was beneficial to flush them with water, or lemon and water with a small quantity of cream of tartar. This treatment by deprivation of liquids was especially necessary when the oliguria was accompanied by dropsy, local or general. The next indication for the treatment of acute nephritis was to save the kidneys by calling the bowels and the skin into activity. In some cases of acute nephritis where uræmic symptoms were at an early stage developed in a previously healthy and vigorous patient, it was right to bleed to the extent of 15 or 20 ounces from the arm or, as Baccelli had suggested, from the dorsal vein of the foot. In addition to local or general depletion the use of hot-air baths, hot packs, or hot baths was advisable, and in most acute cases of albuminuria or of dropsy this treatment alone would be followed by diuresis. The state of high tension of the arteries might be reduced and regulated by a systematic use of nitroglycerine, trinitrites, or sodium nitrite for weeks and months, as under their use tension was reduced and the left ventricle was enabled to recover from a state of dilatation to the normal state of hypertrophy present in cirrhosis of the kidney.

Dr. HENRY C. EARL read a paper on the Pathology of Nephritis. He confined his attention principally to three main points—(1) the etiology of nephritis, (2) the classification of the varieties, and (3) the changes in the cardio-vascular system.—Dr. R. TRAVERS SMITH said that in nephritis nature had two lines of defence, namely, (1) high arterial tension and hypertrophy of the left ventricle, and (2) œdema. Looking upon œdema, as well as upon high arterial tension, as conservative processes, he thought that there were certain cases of extremely severe uræmic symptoms where it might be a good thing to induce œdema. He had given sodium chloride to a man who had been for some time in uræmic convulsions and coma, with the result that at the end of 24 hours he became markedly œdematous and made a good recovery from all his symptoms.—Sir JOHN W. MOORE said that he concurred with the view put forward by Dr. Travers Smith as to the beneficial influence of œdema in cases of chronic renal disease, with regard to which he had read a paper before the British Medical Association at the Oxford meeting.

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held on Jan. 15th, Dr. J. A. Dewar, Vice-President, being in the chair.—Dr. W. J. Dewar showed a boy, aged ten years, the subject of Hæmophilia, who always bled for about three weeks after any cut; a maternal uncle and a younger brother were also affected with the disease. He also showed a boy, aged seven years, the third of the family to be affected with Club foot.—Dr. J. D. Gilruth showed a young woman who seven years ago had a Gastric Ulcer excised but who since then had periodic attacks of severe pain and vomiting probably caused by adhesion of the stomach wall to the parietes. In May, 1907, Mr. D. M. Greig performed an anterior gastro-enterostomy and since then the patient had remained free from all her former discomfort. —Dr. Gilruth also showed a man, aged 35 years, who had suffered for some years from an Ulcer of the Duodenum upon whom a posterior gastro enterostomy had been performed.—Dr. Middleton Connon showed specimens of a Salivary Calculus and an Unusual Fœtal Monster in which could be *seen only one foot*, no *legs*, arms, or hands. It was a twin pregnancy and the first born was a healthy well-formed live male child.—Mr. Greig read a paper on Ankylosis after *Dislocation of the Elbow*. He stated that up to recent times considerable doubt existed as to the true cause of such conditions. It had been frequently observed that after an ordinary simple dislocation backwards of both bones at the elbow considerable stiffness with very limited movement at the joint sometimes occurred several weeks after the dislocation had been reduced; this was generally said to be due to a fracture into the joint. Since the advent of x rays it was now possible to determine at the time of the accident if any fracture existed. He described and discussed two cases in detail, including the origin of new bone formation after these injuries such as had caused the ankylosis in his second case and mentioned the theories that had been propounded to account for its was limited to one-half the natural extent and the abduction to 45° in the case of complete excision. A posterior T-shaped incision was used and through that the three groups of large vessels were tied early in the operation to minimise hæmorrhage. It was claimed that preservation of the processes and glenoid cavity was both practicable and advisable in preference to complete excision of the scapula for inflammatory conditions and innocent growths and possibly for some malignant growths.

Mr. **OPENSHAW** showed a case of Multiple Dislocations, including congenital dislocation of both hips, in a child two weeks old, incontestably the result of malposition in utero. The patient was taken to him as an out-patient at the London Hospital on Feb. 7th last presenting dislocation of both shoulders, both elbows, both hips, and both knees, and extreme double equino-cavo-varus. The child otherwise was well formed; the cranium presented no deformity. There were a large umbilical hernia and a history of snuffles. The mother had five other children and had had three miscarriages. The position in which the child lay in utero could be definitely reconstructed. The limbs in their abnormal position fitted closely to the body; the hips fully flexed, the knees hyper-extended, and the feet twisted into the position of equino-varus. The arms were flexed and rotated in at the shoulders and the hands were situated in the armpits in a position of acute flexion at the wrists. The head and neck of the right femur were rotated outwards upon the shaft to an angle of 30°. The head was dislocated and lay outside, and in front of, the anterior superior spine. The thigh was acutely flexed on the abdomen, the inner surface of the femur resting in contact with the abdomen. The condyles were visible in the popliteal space, the knee being retroflexed to an angle of 100°. The knee could only be flexed even with force to an angle of 160° and immediately dropped back to an angle of retroflexion of 110°. There was extreme congenital equino-varus, the os calcis resting on the leg and the sole of the foot looked upwards. The scaphoid was the lowest bone of the tarsus. The left leg presented a similar condition, except that the knee was hyper-extended to an angle of 110° and could only be flexed to an angle of 170°. The left foot presented the same condition as the right; the scaphoid was the lowest bone. There was a large funnel-shaped umbilical hernia which bulged between the knees when the legs were in the position in which they were in utero. There was a subcoracoid dislocation of the right shoulder. At the right elbow both bones were dislocated backwards and outwards. There was marked pronation of the right forearm. The fingers were well formed but excessively hyper-flexed at the metacarpo-phalangeal joints. The transverse metacarpal ligaments were extremely stretched, so that the heads of the metacarpals could be separated and the hand stretched out to a width equal to double the length of the palm. The left arm presented a similar condition. Mr. Openshaw considered that it was incontestably a case of congenital dislocation of hips, knees, shoulders, and elbows from intra-uterine malposition. He had seen two other cases where congenital dislocation of the hip had been associated with congenital recurvation of the knee and talipes in the same leg due to intra-uterine malposition and pressure.

Mr. **O. A. R. NITCH** showed a case of *Myositis Ossificans* in a girl, aged 10 years. The disease commenced in the muscles of the neck when the child was aged three and a half years and within a few months the pectoral, scapular, and lumbar muscles were involved. Plaques, bosses, and spicules of bone could be felt in the following muscles: the erector spinæ, latissimus dorsi, trapezius, and pectorales of both sides; the right rhomboideus major and minor, the left rhomboideus minor, the left levator anguli scapulæ, the left infra-spinatus, the geniohyoid, the sterno-mastoids, the right vastus externus, and the muscles in the popliteal space. Microdactyly of both great toes was present. The back and neck were now quite rigid, movements at the shoulder-joints were very limited, full extension of the right leg was impossible, and owing to the fixation of the thorax respiration was purely diaphragmatic.

Dr. **F. E. BATTEN** and Dr. **J. GRAHAM FORBES** communicated a note on two cases of Infection with the Bacillus Enteritidis of Gaertner. They described two cases of prolonged fever and diarrhœa in infants, the blood of whom, though repeatedly tested, gave a negative Widal reaction. The first was that of a child, aged 12 months, in whom the disease lasted for 35 days. On the nineteenth day the blood was tested with the bacillus enteritidis of Gaertner and gave a marked reaction. Purpura developed during the course of the disease. The child died and at the necropsy numerous ulcers were found throughout the small intestine. A pure growth of a Gram-negative motile bacillus was obtained from the spleen and mesenteric glands. The organism gave the characteristic reaction of the bacillus enteritidis of Gaertner. The second case was similar but towards the termination developed symptoms suggestive of a general tuberculous infection. The child died and at the necropsy no evidence of tuberculosis was found. The bacillus enteritidis of Gaertner was isolated from the stools.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Feb. 7th, Dr. **J. BARRY BALL**, the President, being in the chair.

The following cases and specimens were shown:—

Dr. **F. PARKES WEBER**: A case of Multiple Hereditary Developmental Angiomata (telangiectases).

Sir **FELIX SEMON** (for Dr. **SIDNEY P. PHILLIPS**): A case of Multiple Telangiectases.

Dr. **A. BROWN KELLY**: Sketches of three patients with Multiple Telangiectases.

Dr. **J. DONELAN**: (1) Specimen and microscopic sections of a Tumour of the Thyroid Gland from a case shown at the last meeting; and (2) a case of Intranasal Hypertrophy associated with continual sweating of the nose.

Dr. **STCLAIR THOMSON**: (1) A case of Syphilitic Pachydermia; (2) a case of Proptosis due to distension of the frontal sinus; and (3) a radiograph to show how the orbito-ethmoidal and frontal cells can be defined before operation.

Dr. **P. WATSON WILLIAMS**: (1) Microscopic sections illustrating the pathogenesis of some forms of Nasal Polypi; and (2) a universal Laryngeal Forceps for use by the direct and indirect methods.

Dr. **W. JOBSON HORNE**: A case of Unilateral Paralysis of the Tongue.

Mr. **W. J. CHICHELE NOURSE**: (1) A case of Sarcoma of the Nose after operation; and (2) a case of Epithelioma of the Tongue and Fauces after operation.

Mr. **W. STUART-LOW**: A case of Complete Closure of the Anterior Nares with Partial Atresia of the Pharynx; and (2) cases after the Radical Maxillary Antrum Operation exemplifying a simplification of the after-treatment.

Dr. **ANDREW WYLIE**: A case of Swelling of the Arytenoid.

Mr. **HERBERT TILLEY**: A case of Early Epithelioma of the Vocal Cord.

Mr. **C. A. B. HORSFORD**: A girl, aged 17 years, with a baritone voice.

Dr. **DAN MCKENZIE**: A case after removal of an Endothelioma of the Palate.

Dr. **J. DUNDAS GRANT** and Dr. **DAN MCKENZIE**: A case after operation for Median Cervical Fistula.

Dr. **W. H. KELSON**: A case of Nasal Ulceration.

Dr. **DUNDAS GRANT**: A case of Epithelioma of the Fauces.

Dr. **G. WILLIAM HILL**: A case of Laryngeal Tuberculosis.

OPHTHALMOLOGICAL SOCIETY.

Some Primary Facts of Colour Perception.—Exhibition of Cases.

A CLINICAL evening of this society was held on Feb. 13th, Mr. **E. TREACHER COLLINS** being in the chair.

Dr. **F. W. EDRIDGE-GREEN** gave a lantern demonstration on Some Primary Facts of Colour Perception, and an interesting discussion resulted in a resolution being passed, on the proposition of Mr. **C. D. MARSHALL**, that a committee of the society should be appointed to go into the question of colour-blindness and the tests for its detection and to report to the society.

Mr. **L. J. PATON** showed a case of Detachment of the Retina treated by operation. The patient abd been sent to the National Hospital for the Paralysed and Epileptic with the diagnosis of double optic neuritis and the remark that both nasal fields were lost. The right eye had been useless for 36 years and for a year there was mistiness in the *left*. Vision was then $\frac{6}{60}$; now it was $\frac{6}{18}$. To get at the main point of detachment he trephined above the tendon of the external rectus and pulled the eye well forward by a tenotomy hook under the external rectus. He cauterised through the sclera until the subretinal lymphaticus, as such patients needed special care when being anæsthetised.—Dr. F. W. Hewitt regarded the whole question as most pressing, for many of the deaths just previously narrated were preventable. The older view, that a small number of deaths is inevitable, was incorrect. Anæsthetics were not dangerous drugs unless placed in incompetent hands. The facts of the case should be stated plainly. The conditions ceased to exist as dangers when experience had been profitably gained with the use of these drugs. In fatal cases the fault did not rest with the surgeon, the patient, the operation, or the drug. The principle to be followed was that the respiratory functions were affected: the anæsthetised patient might suffer from an intercurrent asphyxia, especially in cases in which the respiration was liable to be spasmodic. On the post-mortem table no evidence of this spasmodic condition might be manifest. Much greater and more special attention should be given to the practice of anæsthetics in medical schools. He doubted if sudden cardiac and circulatory failure was ever fatal in such circumstances. "Fatty heart" was now rarely offered as the cause of death; status lymphaticus might also before long cease to be suggested. The real cause of death was auto-asphyxiation which could be guarded against if very special care was taken by the anæsthetist.—Mr. R. Henslowe Wellington did not think that 74 cases was relatively a large number in six years' inquest practice, especially as several were merely coincidental with the anæsthetisation.—Dr. Leonard E. Hill affirmed that the danger lay in paralysis of the heart. The vagus nerve centre was rendered irritable by the drug and the nerve itself was excited; the failure of respiration was due to the great fall of the blood pressure owing to the gradual poisoning of the heart. The heart could not be revived after paralytic dilatation unless it was infused with normal blood. A mechanical contrivance must be invented whereby a safe dose of the drug could be given.—Mr. John Troutbeck explained how the cases had come under his notice as coroner for one-eighth of the metropolis. Few deaths under anæsthetics were reported by private medical practitioners, possibly because it was not generally known in the profession that all such cases must be considered by the inquest jury. The anæsthetist should be a person in authority and not a junior practitioner whose freedom was biassed by the expressions of opinion of a senior surgeon. Very seldom did the relatives complain in hospital cases. A pathologist should be instructed to investigate the case who was neither the anæsthetist nor the surgeon interested, although both the latter should be allowed to be present at the necropsy and to give evidence. He had not gained much help from the lists of questions which had been published from time to time as a guide in these cases. Each coroner after some experience learnt what questions it was most profitable to put.—As the discussion had aroused great interest it was decided, on the motion of Dr. F. J. Smith, seconded by Dr. F. S. Toogood, to adjourn the meeting until Tuesday, March 24th, at which session certain medico-legal aspects of the question will be discussed. Mr. Justice Walton, the President, will be in the chair.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 5th, Dr. L. W. Marshall, the President, being in the chair.—Mr. R. G. Hogarth showed a boy, aged seven years, the subject of Multiple Exostoses affecting the Ribs, Phalanges, Radius and Ulna at the Wrist, Tibia and Femur. A complete removal had been made of all present four years ago, but in view of their painlessness and rapid recurrence no further operation was now contemplated.—Dr. F. H. Jacob showed a breast-fed child, eight months old, who was a well-marked case of Urticaria Pigmentosa. The rash dated from birth and previously to vaccination.—Mr. W. Morley Willis and Dr. J. H. Thompson showed a girl, aged 15 years, in whose breast a painless, globular, vascular Tumour probably of sarcomatous nature had appeared a few weeks before. She had menstruated four times; a slight enlargement of an axillary gland could be made out and a somewhat cystic feel was given by the tumour in places.—The cases were discussed by the President, Mr. Willis, Mr. Hogarth, Dr. J. A. O. Briggs, Dr. Thompson, Dr. J. Watson, and others.—Dr. C. H. Cattle read a paper on Some *Difficulties* in the Diagnosis of Mediastinal Tumours. Practically these resolved themselves into the question as to aneurysm or *tumour*, the latter in the vast majority of cases being of a malignant nature. Referring to the case of a man, aged 58 years, who had been in hospital for three months under observation, it was remarked that many of the symptoms and signs usually associated with aneurysm might at times be due to tumour. Eventually, as the post-mortem specimen showed, the growth surrounded the heart and thoracic aorta, so as to exert pressure upon the left recurrent laryngeal nerve, the left bronchus, and the sympathetic nerves. There were also a systolic basal murmur, an accentuated second sound, and increased pulsation to the left of the sternum, all due to the growth enveloping the aorta and causing shrinkage and compression of the left lung. Whilst in hospital this patient gained steadily in weight. Another sign met with was compression of the left subclavian vein and enlarged superficial veins about the thorax and shoulder. This was distinctly in favour of tumour. A new growth surrounded, compressed, and invaded the veins, while an aneurysmal sac more frequently displaced them. On the other hand, alterations of the arterial circulation—*e.g.*, in the radial pulse—were in favour of a diagnosis of aneurysm. A second case was related occurring in a man, aged 34 years, whose symptoms began with breathlessness and expectoration of blood-stained phlegm. The evening temperature varied between 102° and 104° F. and often remitted as much as 3° in the morning. Friction-sounds were heard near the left nipple and in the lower axillary region. When admitted he was pale and wasted, short of breath, and unable to get about. He was hoarse and the left vocal cord was paralysed. There was dulness at the left apex in front and at the base behind. The breath-sounds were weak over the left lung in general, but of tubular quality at the apex. Pain was practically absent, but there were attacks of spasmodic cough. The puzzling features of the case were the rapid wasting, marked adynamia, and the hectic temperature without much expectoration. After an illness lasting for about four months the patient died suddenly from a profuse hæmorrhage. The clinical symptoms were thought to have pointed to rapidly growing sarcoma of the lung. At the necropsy the right lung was found greatly distended and the left was collapsed. A small aneurysm had compressed the left bronchus close to the bifurcation of the trachea, into which it had ruptured. The left pleural cavity contained three-quarters of a pint of fluid and the *visceral pleura* was thickly coated with recent fibrin.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Feb. 5th, Dr. A. T. Wilkinson, the President, being in the chair.—The President read a paper opening a discussion on Alcoholic Cirrhosis of the Liver. He urged that due recognition should be given to tympanites as a diagnostic sign of advanced disease and claimed that this condition was equal in significance to the classical signs of ascites, jaundice, hæmatemesis, and cerebral symptoms. A typical case was described in illustration of this thesis. A tympanites of three weeks' duration in a well-nourished man, aged 36 years, who felt in his usual health, was the sole prominent symptom. Alcoholic cirrhosis was diagnosed and the patient died nine days later from coma. The diagnosis was confirmed by necropsy. The President drew attention to the neglect of this symptom of tympanites by the text-books. In most works the matter was not *mentioned*; in others tympanites was referred to as a sign which might mask others, such as ascites. There was a failure to recognise tympanites as a prominent sign *per se*. The pathology of acute *painless tympanites* in alcoholic cirrhosis was then discussed and the condition was attributed to back pressure from the portal system whereby the delicate neuro-muscular apparatus of the intestine was thrown out of gear. In speaking of the treatment of advanced hepatic cirrhosis the time-honoured pill of mercury, squill, and digitalis, of each 1 grain, was advised as the most trustworthy diuretic. As regards the etiology of cirrhosis the President declared his belief in alcohol as the causative agent to be unshaken. It was the steady "sober" *drinkers*, not the habitually *drunken* who filled our inebriate homes, who were the victims of alcoholic cirrhosis. A brain sensitive to alcohol was actually a safeguard against alcoholic cirrhosis. *Gastric catarrh* did not, in his experience, bear any causative relation to cirrhosis. It was those who "stood alcohol well" who suffered from this hepatic change.—Dr. E. S. Reynolds agreed with the President as to the different susceptibility of the "drinker" as distinguished from the "drunkard" to alcoholic cirrhosis. He believed hepatic cirrhosis to be not uncommon in children, their livers being specially susceptible to alcohol. Splenic enlargement was inversely proportional to the amount of ascites. In ascites he believed tapping should be persevered with;

LIVERPOOL MEDICAL INSTITUTION.

The Treatment of Hæmoptysis by Nitrite of Amyl.—The Physiological Importance of the Calcium Salts.

A MEETING of this society was held on Feb. 13th, Mr. T. H. BICKERTON, the President, being in the chair.

Dr. G. A. CRACE-CALVERT read a note on the Treatment of Hæmoptysis by Nitrite of Amyl. He stated that until recently the treatment of hæmoptysis had not been satisfactory and that nearly all drugs except morphine had been described as useless. Dr. F. W. E. Hare had called attention to the use of the nitrite in checking hæmorrhage and pointed out that it acted partly by causing a marked reduction in the arterial blood pressure and partly by producing an intense anæmia of the lung parenchyma, and so gave time for clotting to take place. Dr. Crace-Calvert had tried it in about 25 attacks of hæmoptysis—many of them profuse—and always found that it checked the bleeding almost instantly. Afterwards if there was excitement of any kind he gave a quarter of a grain of morphine. He considered that nitrite of amyl was the drug *par excellence* to be used first, as it saved the patient unnecessary loss of blood and prevented large accumulations of blood in the air passages. It was especially useful in sanatorium work where the patient was seen at the beginning of the attack.—Sir JAMES BARR congratulated Dr. Crace-Calvert upon pointing out the value to be obtained from the use of nitrite of amyl and such other agents in cases of hæmoptysis. He said that they often heard of blood pressure in numerous diseases without the observers having any clear idea as to what was meant by blood pressure. Blood pressure was purely a relative term, and what might be considered a very high blood pressure in pulmonary tuberculosis would be a low pressure in renal disease. In pulmonary tuberculosis the heart was small and weak, and a comparatively small resistance was more than it could cope with; therefore any slight rise in the arterial pressure in cases of pulmonary tuberculosis was very apt to dam back the blood in the pulmonic system. The great advantage of the use of morphine or morphine and atropine in cases of pulmonary tuberculosis arose from the fact that they generally stopped the cough and thus prevented any rise in the arterial pressure. Personally he had for many years used nitro glycerine in cases of hæmoptysis and as a rule he preferred it to nitrite of amyl because of its more lasting effect. If the blood was deficient in lime salts it was very important that lime salts should be administered.—Dr. NATHAN RAW could not agree that nitrite of amyl had any specific action in the control of hæmoptysis. Whilst one occasionally met with an overpowering hæmorrhage which was rapidly fatal, the fact remained that the great majority subsided spontaneously with care and rest. He could not agree that hæmoptysis was due to increased blood pressure, but rather to erosion of some small blood-vessel. He advocated absolute rest in the recumbent posture, a hypodermic injection of morphine, ice to suck, and cold turpentine applications to the chest. He had seen excellent results from adrenalin chloride in long-continued but small hæmorrhages from the lungs. By lowering the blood pressure it was possible that nitrite of amyl was occasionally useful.—Dr. W. B. WARRINGTON said it had long been recognised that a hypodermic injection of morphine was the most satisfactory drug in the treatment of hæmoptysis and for some years past nitrite of amyl in addition had been the routine treatment at the Northern Hospital.—Dr. A. G. GULLAN said that there seemed to be varied opinions on the blood pressure of pulmonary tuberculosis and he believed that in many cases it was lowered. Yet everyone was well acquainted with the excited and strong action of the heart and the strong and quick pulse which arose on the sudden occurrence of a serious hæmoptysis. The arterial blood pressure was then undoubtedly greatly increased and it was in this condition that the amyl nitrite was beneficial as a rapid means of lowering it. At the same time such good results had been obtained by rest, morphine, and purgatives in the past, and moreover these methods were invariably used in conjunction with amyl nitrite, that he felt too much credit for the good results obtained should not be given to that drug.—Dr. R. J. M. BUCHANAN drew attention to the fact that cases of pulmonary tuberculosis associated with good blood pressure generally did well and that hæmoptysis more often occurred in chronic and relatively favourable cases. The hæmoptysis was in a large majority of cases the result of raised blood pressure in the systemic arteries, and nature pointed out a method of treatment in that the hæmoptysis itself lowered pressure and thus arrested hæmorrhage. Taking the lesson from nature, the use of nitrite of amyl acting in the same way was a rational therapeutic measure and the results justified its administration.—The PRESIDENT, Dr. T. BUSHBY, Dr. T. R. BRADSHAW, and Dr. J. H. ABRAM also took part in the discussion, and Dr. CRACE-CALVERT replied.

Dr. W. BLAIR BELL read a paper on Some Observations on the Physiological Importance of the Calcium Salts. He said that his observations had been made incidentally during the work he was at present engaged upon in reference to the calcium metabolism in menstruation and pregnancy, and he considered them of sufficient importance to bring forward as he himself could not carry them any further. His method of calcium estimation, already described,[1] had been largely employed in the investigation. The diurnal variations and the value to be attached to the blood index and the interpretation thereof were fully described. He discussed what he described as the reparative function of calcium salts and stated that he considered there was always a determination of these salts to an injured or a diseased region. He also thought that there was no such thing as calcareous degeneration *per se*, but rather calcification—a reparative process—in diseased structures. The effect which lime salts had upon involuntary muscles was next mentioned and Dr. Blair Bell alluded to the work of Ringer and others in this direction. He went on to describe the attempts made by himself to discover the regulating factors in the calcium metabolism, and discussed his experiments and observations in regard to the thyroid, pituitary, and other ductless glands, which he considered acted in association, anabolically or katabolically, in connexion with the lime salts. The question of calcium and the coagulability of the blood was discussed and he brought forward evidence to show that the reduction of the coagulability of the blood on the administration of an excess of lime salts was due not to an excess in the blood but to an active resistance or immunity on the part of the subject, or increased excretion brought about probably by thyroid interference. The power which the leucocytes possessed of absorbing calcium probably in solution, and conveying it for the processes of repair and for other functions, was considered and evidence was adduced to show the probability of this property. Lastly, Dr. Blair Bell described some interesting observations upon gelatin and the contained calcium. He illustrated the fact which he had discovered that if calcium is precipitated from gelatin it will no longer coagulate by passing round a control and a specimen prepared several days before.—Sir JAMES BARR said that he considered this one of the most important papers that he had heard for a long time. He had himself been using calcium in disease for many years, and therefore felt very grateful to Dr. Blair Bell for giving a more accurate method for estimating the amount of calcium in the blood. Hitherto they had had to go by the coagulability of the blood, and in such a disease as pneumonia by the amount of the adhesiveness of the secretion. In cases of pneumonia it had a very great value, especially in those cases in which the secretion was liquid or hæmorrhagic. *Cæteris paribus*, the more scanty and viscid the expectoration in pneumonia the better the prognosis; hence in such a disease he had condemned the use of expectorants for many years. The calcium salts had a wonderful effect not only in increasing the secretion but in toning up the vessels. The variable amount of lime salts in the blood at different periods of the day scarcely affected the diseased conditions, because in the infective process the calcium was thrown out of the blood into the tissues, and in such cases there was always a tendency to a deficiency. Sir James Barr also discussed the action of calcium on the blood and circulation.—Dr. BUCHANAN considered Dr. Blair Bell's method of calcimetry by the use of the hæmocytometer sufficiently accurate for clinical purposes and that it stood on a par with erythrocytometry and leucocytometry in abnormal blood states.—Dr. P. HICK said that although the total calcium of the blood was not precipitated by Dr. Blair Bell's method, all the "ionised" calcium was, and that it was in this state that the calcium took part in such active processes as the clotting of blood, and the method gave a measure of the available calcium. Also that the calcium chloride and calcium lactate given by the mouth occasionally gave no that bougies should only be employed by experts. The chapter on acute inflammation of the middle ear contains quite a full account of the subject. Chronic middle-ear suppuration, together with its complications and sequelæ, is very fully described. The remaining chapters deal with diseases of the internal ear, specific diseases of the ear, deaf-mutism, and allied diseases of the nose and naso-pharynx, and are quite up to the standard of the rest of the book.

---

[1] Brit. Med. Jour., April 20th, 1907.

We consider that this work is one well adapted to supply the needs of the student and as a handbook of reference for the general practitioner.

LIBRARY TABLE.

Text-book of Organic Chemistry for Medical Students. By Dr. G. von BUNGE, Professor of Physiological Chemistry in the University of Basle. Translated, with Additions, by R. H. ADERS PLIMMER, D.Sc. Lond. London: Longmans, Green, and Co. 1907. Pp. 260. Price 6*s.* net.—Professor Bunge's well-known faculty of presenting the principles and facts of chemistry in general, and of organic chemistry in particular, in a clear light has always gained for him a large circle of readers. Moreover, his experience in his position of professor of physiological chemistry in the University of Basle has brought him into contact with the needs of medical students in regard to that knowledge which is most useful to them in connexion with their particular study. There can be no doubt, as he says, that the domain of organic chemistry has been widened to such an enormous extent by the increasing labours of the last decades that those who devote their life to the study of organic chemistry can no longer be masters of the whole subject. If that be so it is obvious that the position of the medical student in regard to making a sound acquaintance with the facts and principles of organic chemistry grows increasingly difficult year by year. Yet he is necessarily compelled to acquire some knowledge, as otherwise his study of physiology, pathology, and so forth will be beset with obstacles. The fact is that he has to pick out for himself those portions of the science which bear more intimately on his medical studies. The purpose of this volume, in short, is to save him the labour of consulting voluminous works on the subject and to bring him into contact with just those points which concern him most as a student of medicine. In these days of rapid advances this crystallising process is obviously difficult, but in the hands of such an experienced teacher as Professor Bunge a groundwork at any rate is laid which is sufficient for the purpose in view, while of course the student if he should demand more can afterwards devote himself to more comprehensive works on the subject. We can congratulate the student who starts the strictly medical side of his studies with such an excellent knowledge of principles and facts as is outlined in this readable treatise. He further will appreciate the fact that the translator has made several additions which were introduced to meet the extra requirements of the English curriculum as compared with the German. As a companion to physiological and pathological study the book will be found most useful.

JOURNALS AND MAGAZINES.

Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XXXVI., Nos. 4 and 5. Dec. 31st, 1907. London: C. F. Clay. Price 10*s.*—The following are the contents of the two numbers of this journal. 1. F. S. Locke and O. Rosenheim: Contributions to the Physiology of the Isolated Heart: the Consumption of Dextrose by Mammalian Cardiac Muscle. 2. W. M. Bayliss: Researches on the Nature of Enzyme Action on the Causes of the Rise in Electrical Conductivity under the Action of Trypsin. 3. Lucas Keith: On the Rate of Variation of the Exciting Current as a Factor in Electric Excitation. 4. J. Barcroft and G. R. Mines: The Effect of Hirudin upon the Gases in Arterial Blood. 5. A. E. Boycott and G. C. C. Damant: A Note on the Quantities of Marsh Gas, Hydrogen, and Carbon Dioxide produced in the Alimentary Canal of Goats. 6. John Mellanby: The Precipitation of the Proteins of Horse Serum. 7. Keith Lucas and G. R. Mines: Temperature and Excitability. 8. J. N. Langley: On the Contraction of Muscle Chiefly in Relation to the Presence of Receptive Substances. Part 1.

The Quarterly Journal of Microscopical Science. Edited by Sir E. RAY LANKESTER, K.C.B., F.R.S., with the coöperation of ADAM SEDGWICK, M.A., F.R.S., SYDNEY J. HICKSON, M.A., F.R.S., and E. A. MINCHIN, M.A. With lithographic plates and text figures. New Series, No. 205. Vol. LII., Part 1. London: J. and A. Churchill. Price 10*s.* net.—The contents of this part of the journal are: 1. Spirochæta (Trypanosoma) Balbiani (Certes) and Spirochæta Anodontæ (Keysselitz); their Movements, Structure, and Affinities, by H. B. Fantham, B.Sc. Lond., Derby Research Scholar, University College, London, with three plates and 11 text figures. 2. The Structure and Life-History of Copromonas Subtilis, *nov. gen. et nov. spec.*; a contribution to our knowledge of the Flagellata, by C. Clifford Dobell, B.A., Scholar of Trinity College, Cambridge, with two plates and three text figures. 3. Notes on some Parasitic Protists, by C. Clifford Dobell, with a plate. 4. Studies in Spicule Formation: VIII., Some Observations on the Scleroblastic Development of Hexactinellid and other Siliceous Sponge Spicules, by W. Woodland, the Zoological Laboratory, King's College, London, with a plate. Mr. Fantham's memoir on the spirochæta Balbiani and spirochæta anodontæ is of great interest. It contains a good historical introduction. The specimens were obtained from English oysters, in which they occupy in particular the crystalline style and adjoining parts, few being found in the posterior part of the intestine or in the rectum. A ½ per cent. solution of methylene blue was found to be a useful *intra vitam* stain. The gut contents were fixed as quickly as possible and while still wet with osmic vapour. Of the various stains tried on fixed material the most successful results were obtained with alcoholic gentian violet, iron-alum hæmatoxylin, and other hæmatoxylin solutions. The length of the spirochæta Balbiani is from 150μ to 50μ and it is 3μ to 2μ in breadth. It is composed of homogeneous protoplasm and a nucleoid composed of about 60 rodlets of chromatin disposed transversely along the body at nearly equal distances. Attached to the body of the animal is an organella or spirally wound membrane, which is longitudinally striated and executes undulating movements with great speed. The movement of the organism as a whole is in jerks and partly results from a spiral thrusting motion due to the membrane and partly to an undulatory flexion of the body due to contractions of myonema fibrils of the periplast. Various forms of movement are described. The animals live by endosmosis. A very carefully drawn up account of the changes observed in the nucleus in division is given. The drawings which accompany the memoir are very interesting and show how much may be learned of the structure of extremely minute organisms. Mr. Dobell's article on Copromonas Subtilis is also full of interest and is well illustrated.

Journal of Anatomy and Physiology. Conducted by Sir WM. TURNER, K.C.B., ALEX. MACALISTER, D. J. CUNNINGHAM, ARTHUR THOMSON, and ARTHUR KEITH. Vol. XLII., Third Series. Vol. III., Part 2. London: Charles Griffin and Co. January, 1908.—It was intended that this part should be the first of a journal of physiology published separately from a journal of anatomy but it has been found to be impracticable to break up the well-known *Journal of Anatomy* occurrence, of which he had no doubt. Loss of resilience in the soft parts from the swelling associated with a tearing away of the periosteal attachment of the muscle in the efforts to reduce the dislocation had been the starting point of the new growth which, like callus, was derived from the osteoblasts of the periosteum. He discussed the treatment which he intended to adopt and by removing this new growth of bone he hoped to get a good result. He mentioned how careful one had to be when seeing an old injury to the elbow in which there was stiffness not to conclude that there had been a fracture when no opportunity had been given to see an x ray photograph of the condition before and after reduction.—Dr. G. A. Pirie then gave an account of the Routine Use of X Ray Photography in Private Practice and exhibited a series of photographs showing many interesting conditions in bones and chest which had occurred in his practice.——A meeting of this society was held on Feb. 6th, Professor A. M. Stalker being in the chair.—Mr. Greig showed a man after Excision of the Patella for a Chronic Periostitis of that bone. He had been invalided from the naval service as unfit, but as a result of the operation he had once more a perfectly useful limb. On comparing the legs the only visible difference was a diminution in the size of the quadriceps muscle. He commented on the rarity of the operation.—Dr. W. E. Foggie showed a man, aged 48 years, who had syphilis when 28 years of age. Two and a half years ago he had a fall from a horse injuring his right ankle. After this a progressive muscular weakness set in, first in the right leg and passing to the left. Then the right and the left arms became affected and he now exhibited all the symptoms of progressive muscular atrophy, the unusual feature being the onset in the lower limbs following the accident.—Dr. J. S. Y. Rogers showed a man with well-marked symptoms of Raynaud's disease who had been treated for 12 months with x rays for an ulcer in the ear said to be lupus but which was probably Raynaud's gangrene.—Dr. G. F. Whyte showed a man with small ulcers (Raynaud's gangrene) on both ears, who exhibited signs of that disease in both hands, the hands having been affected for several weeks with coldness and stiffness before the ear conditions developed.—Dr. A. J. Duncan read notes on the successful treatment of an obstinate case of Sciatica in a woman by the subcutaneous injection of air. The condition had existed in the left leg for four months and had resisted all the ordinary methods of treatment by drugs, the pain, which was so severe as to cause loss of sleep, only being relieved by morphine. The method adopted was that recommended by Dr. A. S. Gubb of Algiers.[1] Air was pumped into the tissues along the line of the nerve till a condition resembling surgical emphysema was produced. Repeated at intervals of three and five days, this followed by massage of the parts quickly resulted in a diminution of the pain. He quoted in further detail from Dr. Gubb's paper, in which he mentioned many successful cases, and thought that the method was worthy of a further trial.—Dr. G. T. Guild read notes on two cases of Cholesteatoma of the Temporal Bone. He said that some authorities regarded these formations as inflammatory products, others as tumours derived from endothelium, and called them endotheliomata, but Ziegler was of opinion that they had an origin from epidermic epithelium. In the ear they generally occurred during the course of chronic suppuration of the middle ear and were accompanied by a fœtid discharge which might be very scanty and apt to be overlooked. They tended to increase slowly in size and to cause destruction of the mastoid cells and walls of the antrum.—Dr. J. Rogers read notes on a case of Multiple Arthritis which he showed. The patient was a boy, aged six and a half years. He discussed the diagnosis of such conditions.—Dr. G. Halley described two unusual cases of Inguinal Hernia upon which he had operated.—Dr. Whyte described a case upon which he operated similar in many ways to one of Dr. Halley's cases.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 6th, Dr. George Williamson, the President, being in the chair.—Dr. J. Wallace Milne described two cases of Resection of the Bowel for the relief of acute obstruction supervening in a chronic condition of partial obstruction. The first case was that of a girl, aged 10 years, who was admitted to the Aberdeen Royal Infirmary with an intussusception of six days' standing. As the obstruction was not complete and her symptoms were not urgent Dr. Milne resolved to watch the case. On the seventh day after admission the patient developed symptoms of acute obstruction. Laparotomy was performed and an intussusception of the triple or telescopic variety was discovered. The ileum was seen disappearing into the cæcum, carrying with it the appendix. As there were no adhesions, the susceptum was easily expressed from the ascending colon and a tight gangrenous intussusception of the ileum was discovered. This was resected. Upon the forty-fourth day after the operation the patient developed an empyema on the left side. This was treated by resection of a rib and drainage. The subsequent history of the case was good. The second case was that of a male, aged 48 years, who was suffering from symptoms of acute obstruction due to a malignant stricture of the descending colon. The condition of the patient was too bad to permit of resection and a short circuit of the transverse colon to the sigmoid flexure was therefore made by means of Murphy's button. The condition of the patient rapidly improved and on the thirty-sixth day the tumour with six inches of the descending colon was resected. This patient made an uninterrupted recovery. He has gained nearly three stones in weight and has been able to return to work. With the exception of a slight fæcal fistula his general health is excellent.—Professor D. W. Finlay contributed particulars of a case of Chronic Pleuritic Effusion which after two ordinary tappings, yielding respectively 66 and 47 ounces of sero-fibrinous fluid, was treated on four subsequent occasions after Sir James Barr's plan of paracentesis, a solution of adrenalin chloride varying in quantity from one to five drachms (strength 1 in 1000) being injected. The quantities of fluid removed on these four occasions were 47, 75, 70, and 70 ounces respectively. There was a distinct lengthening of the periods between the tappings after the use of the adrenalin, but the pleura had filled up again and there was thus no permanent improvement.—Mr. H. M. W. Gray agreed with Professor Finlay about the adrenalin treatment. He considered that the injection of air into the pleural sac tended to reduce adhesions and to favour expansion of the lung. He was in favour of repeated tappings in such chronic cases rather than resection of the ribs with the risk of empyema.—Dr. G. Rose in this connexion quoted long-standing cases of empyema where cure resulted only after resection of ribs.—Professor Finlay, in reply, described briefly two other cases which required frequent tapping. He was of opinion that in this case resection of the ribs might be tried. He would recommend a tolerably free opening which might subsequently be extended. —Dr. T. C. Mackenzie read a paper on the Recognition and Treatment of Incipient Mental Disease in General and Hospital Practice. He commented upon the importance of treating mental cases in their early and incipient stages. These cases were not provided for under the lunacy law and were as a rule unprovided with hospital treatment. He gave an analysis of the earliest signs and symptoms in cases of insanity recently admitted to the Aberdeen Royal Asylum. Of these, headache, sleeplessness, loss of appetite, general feeling of unwellness, constipation, previous mental attack, and influenza were the most important. In the early recognition of cases of insanity a concurrence of these signs with a history of hereditary predisposition to insanity was of great importance. Dr. Mackenzie then dealt with the recent correspondence in the *Scotsman* concerning "Wards for Incipient Mental Diseases in the Edinburgh Infirmary." Personally, he thought that such wards were very desirable. They had been worked with success in Glasgow and on the continent and he thought that wards of this character, under the charge of a specialist, should be provided in every teaching hospital. He described several cases which illustrated the necessity for hospital wards where acute and transitory cases of mental disorder could be treated without the patient requiring to be certified as insane, instancing such cases as delirium tremens, epileptic confusion and excitement, and some cases of puerperal fever.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on Feb. 11th, Sir William J. Collins, M.P., ex-President, being in the chair.—Dr. L. Freyberger read a paper entitled "An Analysis of 74 Cases of Sudden Death while under the Influence of Anæsthetics." The clinical facts relating to many of these cases, all of which occurred in one coroner's district in the last six years, were given. In each instance Dr. Freyberger had made a post-mortem examination and had given evidence before an inquest jury. In his opinion it was necessary to diagnose the possible presence of status phases of cancer cells which is commended to the perusal of all who are interested in the study of malignant growths.

---

[1] Brit. Med. Jour., Nov. 9th, 1907.

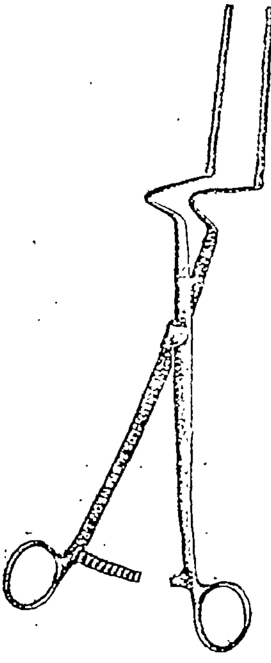
Annals of Otology, Rhinology, and Laryngology, September, 1907.—This number contains ten articles, either original communications or papers which have been read at meetings of societies. The first is by Dr. C. R. Holmes, on the Etiology of Erysipelas and its Relation to the Nasal Cavities, and Destructive Effects upon the Eye. It is a long article of nearly 100 pages and is an interesting *résumé* of the subject. There are three papers on secondary disease of the labyrinth, and several others.

Journal of Laryngology, Rhinology, and Otology. December, 1907.—This number contains two original articles, the first on Tracheo-Bronchoscopy, by Dr. Chevalier Jackson of Pittsburg, and the second, part of an article by Dr. H. M. Fish of Chicago, on a study of 36 consecutive cases of Optic Neuritis, with Nasal Accessory Sinus Disease present in 26.

New Inventions.

ABDOMINAL WOUND SUTURE AND RETRACTOR FORCEPS.

THESE consist of a pair of forceps as seen in the illustration. Two pairs are used, for the right and left sides respectively. They have two flat blades, the lower being the smaller, set on a curved shoulder with long handles and a rack. The blades are tempered so that they meet at the points first and by means of the rack any pressure desirable may be obtained. They are designed for use in the following way. The abdominal wound having been made and the peritoneum opened to the desired extent, the lower blade, or smaller of the right forceps, is introduced and placed parallel to the incision, half an inch from the cut edge on the peritoneal surface; the forceps are then closed and the upper blade presses on the skin parallel to the incision and half an inch removed from it; a firm grasp is thus taken of the one side of the incision. The left forceps is then similarly introduced and fastened. It is then easy for an assistant standing well towards the thighs of the patient to rotate each handle onward, that is to say away from the wound, and thereby to evert the edges of the abdominal wound, at the same time retracting it. If it be thought advisable to protect the edge of the wound in the abdominal wall, as in dealing with some focus of septic matter within the abdomen, this can be accomplished by placing a piece of sterile gauze round the edge of the wound before applying the forceps, when they will hold it firmly in position during any manipulation within. When the wound has to be closed layer to layer, the assistant by a little pressure can approximate the edges of the wound with the cut surfaces everted, so that it is easy to pass a continuous suture along the cut surfaces of the peritoneum and another along aponeurosis or muscle, leaving the last stitch slack until the forceps are released and the lower smaller blades withdrawn, when the stitches may be drawn taut and tied together. This materially facilitates the closing in layers of the abdominal wound and thereby saves time. The forceps could also be used for bowel clamps and would be useful in *enteranastomosis*.



These forceps have been made for me by Messrs. Reynolds and Branson, Limited, of Leeds.

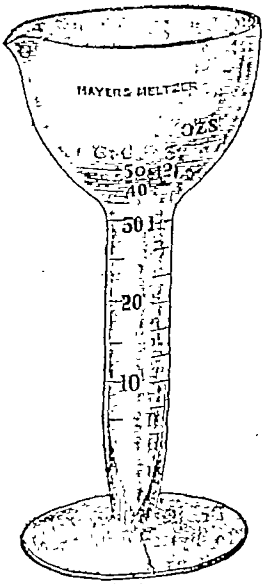
Lancaster.

THE MECHANICAL TREATMENT OF PULMONARY TUBERCULOSIS.

WE have received from the Roborat Company a specimen of Kuhn's Suction Mask for the treatment of pulmonary tuberculosis according to Professor Bier's treatment by passive hyperæmia. The apparatus consists of a light celluloid mask fitting over the mouth and nose, divided by a cross partition into two chambers, for mouth and nose respectively. In both chambers free expiration is permitted by means of valves, while inspiration can occur only through an adjustable slit in the portion allotted to the nose. The margins of the mask are well padded by means of a rubber air tube which causes the minimum of pressure, and the natural nasal inspiration, by means of the slit just referred to, can be impeded in a graduated manner for the desired length of time without discomfort to the patient. Untoward consequences are said not to occur. On placing the mask over the mouth and nose with the slit only slightly open a distinct impediment to free inspiration is experienced. In this manner a certain amount of passive hyperæmia of the lungs is induced; the circulation of the lymph stream, however, is maintained. This method of treatment is stated to have been tried by Professor von Leyden in the medical clinic of the Charité at Berlin with encouraging results. The following effects have been claimed by the use of the mask: improvement of respiration and diminution of dyspnœa; considerable widening of the thorax, reduction of the frequency of respiration, cessation of cough, and disappearance of expectoration, bacilli, and adventitious sounds in the lungs. The colour of the patient improves owing to the improvement of the blood and there is increased appetite. Further, in consequence of the improvement in the circulation, the respiratory musculature is strengthened and the heart's power is raised. We shall watch with interest to ascertain if these results are corroborated by English physicians.

A NEW FORM OF URINE TRIAL GLASS.

THE accompanying illustration represents a modified form of urine trial glass which I have found to be a decided convenience in the examination of the urine of patients and proposers for insurance. The apparatus is well adapted (1) by its wide mouth, to enable urination to be performed into it without splashing; (2) by its narrow calibre, to allow the specific gravity of a minimum amount of urine to be tested; and (3) by the bottom being tapered conically, to facilitate the collection of the sediment. These points have been effectively carried out by the manufacturers, Messrs. Mayer and Meltzer, 71, Great Portland-street, London, W.



R. M. FRASER, B.A., M.B. R.U.I.

Mountpottinger, Belfast.

THE Society of Tropical Pathology of Paris has elected Dr. David N. Nabarro a corresponding member of the society.

this manœuvre was sometimes successful if at the same time alcohol was prohibited.—Mr. M. J. Chevers mentioned a case of "hob-nail liver" in which he had reason to believe the patient had always been a teetotaler.—Dr. F. Craven Moore laid stress on the presence of dilated abdominal veins as a diagnostic feature. He noted the change of form which post-mortem examination in recent years revealed in cirrhotic livers. The old "hob-nailed" liver was now rarely seen, its place being taken by livers of normal size with a granular surface.—Dr. R. W. Marsden thought that this change of type might be due to the change of habits in present-day drinkers.

Reviews and Notices of Books.

Text-book of Comparative General Pathology for Practitioners and Students of Veterinary Medicine. By Professor TH. KITT of Munich. Authorised translation by Dr. WILLIAM W. CADBURY, Assistant Demonstrator of Pathology in the University of Pennsylvania. Edited with notes and additional illustrations by Dr. ALLEN J. SMITH, Professor of Pathology in the University of Pennsylvania. With four coloured plates and 131 illustrations. London: Baillière, Tindall, and Cox. 1906. Pp. 471. Price 25*s.*

IT is a singular fact that great as the contributions afforded to our knowledge of the nature of pathological processes by the study of the natural or experimentally produced diseased conditions of animals have been, most text-books or treatises on general pathology have been written from the standpoint of the practitioner of human medicine and illustrated by reference to the lesions found in the human subject. The veterinary student and practitioner have thus been to some extent at a disadvantage, for although the essentials of pathological processes are closely similar in most mammalia the morbid anatomy and histology of the resulting lesions frequently differ in different animals in very important points. Professor Kitt, recognising that the education of veterinary students, to be rational and scientific, entails as a necessity a study of comparative pathology, set himself the task of writing a text-book on this subject with illustrations of the various morbid processes from the domesticated animals. We may at the outset say that he has succeeded in producing a most valuable book and one which will well repay study from the standpoint of human pathology. A knowledge of comparative pathology is of great value in the elucidation of some of the problems of disease in man, and in view of the great advances which the study of pathology is daily making, and of the valuable additions which it promises to afford to our therapeutic measures, is likely to become of increasing importance. Professor Kitt writes clearly and well and the translator has done full justice to his style, so that the book hardly conveys the impression of having been written in another language. The accounts given of pathological processes and conditions are concise without being sketchy and their results are carefully classified.

A short history of pathology with especial reference to veterinary pathology is given and it is pointed out that research in comparative pathology was completely dormant from the fourth to the eighteenth century. This is followed by a section entitled "Predisposition towards Disease," in which the recent studies on the nature of immunity are summarised and an intelligible and intelligent account of Ehrlich's theories is given. The causes of disease are categorically studied, among which the bacterial agents and the animal parasites are considered in some detail. Among other matters worthy of special mention is the section given up to the description of circulatory disturbances. The accounts of hæmorrhage, dropsy, thrombosis, and embolism are as good as any that we have read. The note contributed by the editor on the conditions leading to the production of anæmic and hæmorrhagic infarcts is especially worthy of notice, for it is much more intelligible than the accounts usually found in text-books of pathology. The retrograde changes and necrotic processes, including the degenerations and infiltrations, are also dealt with at some length, while the descriptions given of these processes and the discussion of their nature are thoroughly commendable.

Perhaps the best criterion for forming an opinion on a text-book of pathology is the account given of the process of inflammation and in this book the account leaves nothing to be desired. It is well written and clearly expressed and the various factors are separately studied, while the results and varieties of the processes are each considered in detail. Like most pathologists, Professor Kitt has his own definition of inflammation and it is a good one. Regenerative and reparative processes are described in detail and an interesting section on tumours follows. Some of the theories of tumour formation are given and luminously criticised.

The book is thoroughly well illustrated, the editorial notes appended are in all cases explanatory of the text, and they are in many instances valuable additions. There are but few misprints, though we notice on p. 259 "ecshars" for "eschars." We can cordially recommend this book to anyone who wishes to gain a clear knowledge of the principles of general pathology from a comparative point of view.

Diseases of the Ear. By HUNTER F. TOD, M.D. Cantab., F.R.C.S. Eng., Aural Surgeon to the London Hospital, &c. Oxford University Press: Henry Frowde. London: Hodder and Stoughton. 1907. Pp. 317. 15 figures and 18 plates. Price 5*s.*

THE first two chapters of this practical book are devoted to the diseases of the external ear and contain a short and useful account of the various diseases and malformations of the part, with their treatment. It is interesting to note here that the view is expressed that the old method of operating by means of a burr for the removal of exostoses through the canal is falling into disuse as being unsurgical as well as dangerous. Cutting away the growth through the meatus by means of a gouge is one of the surgical procedures described. The third chapter is devoted to diseases of the tympanic membrane. Acute myringitis, apart from a traumatic lesion, is described, and, as Mr. Hunter Tod remarks, it is met with clinically, though we cannot say that we consider this sufficient argument for considering myringitis as a separate disease. The fourth chapter deals with diseases of the middle ear and, in common with the preceding ones, is prefaced by a short description of the anatomy of the part. In this chapter the tests for hearing are dealt with. There is a fairly full description of Rinné's test, with some directions as to its application, and after the tests have been discussed and their employment indicated a brief summary is given, and it is stated that in middle-ear deafness "Weber is referred to the affected side, bone conduction is increased, Rinné is negative, &c., while in internal ear deafness bone conduction is diminished," although this does not complete the summary. We think that such a statement should not be made without very considerable qualification. In describing the methods of inflation of the middle ear a very excellent series of reasons is given to show which method is preferable and in what cases. On p. 89, in discussing the time at which inflation of the middle ear may be performed, an unfortunate printer's error causes it to read "64" instead of 48 hours. Chapter V. deals with chronic middle-ear catarrh and contains a very admirable and short account of the disease. In discussing the treatment of it a wise statement is made, many of our readers will follow these articles, even though they have no direct interest in India, for we hold that medical men as a body can exercise a notable influence on public opinion in subjects of which they have special knowledge. A strong body of public influence may materially hasten the time when the Medical Service in India shall be reorganised on lines sufficient for the demands made on it by present conditions.

◆

New Zealand and Public Health.

WE have received a copy of the report of the Department of Public Health for the colony of New Zealand for the year 1906–07, dated June 1st, 1907, and, with its appendices, covering 112 folio pages. A considerable amount of this space, of course, is occupied by matter of a kind undistinguishable from that with which we are familiar at home, such as the statistics of vaccination and other similar matters; but even here attention cannot fail to be arrested by a return which shows the infantile death-rate of the colony to be under 70 per 1000. In this respect it is not uninteresting to note that illegitimate children become legitimatised by the subsequent marriage of the parents, or in any case in which a man marrying a woman with illegitimate children registers them after the marriage as his own. An Act to this effect was carried in 1894 and has been taken advantage of in the case of 849 children; while two years later an Act was passed for the better protection of infant life, by which it was enacted that no one may take charge, for payment, of an infant to maintain or to nurse for more than three days without holding a licence as an "infant's home keeper." The house of every such person must be registered as an infants' home, and all these homes are periodically inspected by the police. The Police Commissioner reports that for the year ending March 31st, 1906, there were 557 of such registered homes in the colony, containing 862 infants, against 528 homes and 728 infants in the year preceding. 21 deaths occurred in the homes during the year and four licensees, three of whom were convicted, were prosecuted for breaches of the Act; but no licence was cancelled and no neglect on the part of licensees was disclosed at inquests. It is difficult, of course, and perhaps impossible, to institute any fair comparison in such matters between the colony and the mother country; but it must at least be admitted that the conditions of infant life there must in many respects be far better than those which exist at home. To take one of these respects only, we read that "there has been no epidemic of any serious nature during the past year." Measles and scarlet fever have occurred in certain districts, but the cases have been limited in number and the deaths few. Vaccination is being largely neglected, over 81 per cent. of the children born during the year under consideration being still unprotected; but the neglect is attributed chiefly to an indifference arising from ignorance of the nature of small-pox. When that disease appeared in Christchurch in 1904 11,120 people were voluntarily vaccinated in three months; and the chief health officer, Dr. J. M. MASON, seems to be of opinion that any manifest danger of a small-pox outbreak would again occasion a rush for protection. In the meanwhile, one of the most pressing dangers to public health appears to arise from the prevalence of hydatids, and special injunctions concerning the precautions to be taken in keeping and feeding dogs occupy a prominent place in the report.

The most remarkable feature of the document, however, and one which might profitably receive careful consideration from the legislatures of older countries, is the history of a campaign against certain forms of dishonesty and of quackery which has been set on foot by the agency of what is described as a "modest and unassuming amendment" to the Postal Act. By this amendment the Postmaster-General of the colony is empowered to issue under his hand an order forbidding the registration, forwarding, or delivery of any letter or postal packet to any specified address, or the issue of any money order to the same address, he having reason to believe that the correspondence thus estopped is part of a system of betting, gambling, professed prediction of future events, of any "fraudulent, obscene, immoral, or unlawful business or undertaking," or of any "advertising in direct or indirect terms the treatment of diseases of the sexual organs." In commenting upon this amendment of the law and upon its effects the chief health officer points out that "most of the vultures who fattened on the fears of the misguided youth or the simplicity of the elderly man about town have, so to speak, been warned off the course." They have, he says, used in defence such weapons as might have been expected. Newspapers have been threatened with loss of revenue, the cry of medical oppression has been raised, and some have attempted bribery, but, in spite of all, he is pleased to place on record that every paper of standing in the colony has not only gladly agreed to accept the Postmaster-General's ruling but has endeavoured in every possible way to throw out advertisements which were demonstrated to be proclaiming wares or services which were not in the best interests of the State. "I have no hesitation," he continues, "in saying that in no part of the world could a cleaner advertisement page be found than in New Zealand." Many of the operators have left the colony and the reasons assigned for their departure are curious and varied. One, because his New Zealand clients have become numerous, has determined to transfer his operations to Sydney, and on account of the greatness of his reputation he asks his New Zealand patients to send their letters to another address and inscribed to another name. "No one," writes the chief health officer, "is foolish enough to believe that quackery and fraud can be stopped entirely, but the inclusion of this section of the Post Office Act Amendment amongst our laws has satisfied me that much can be done."

◆

The Supply of Pure Milk to Hospitals.

THE question of the supply of pure milk to the London hospitals has during the last year been engaging very seriously the attention of the bodies responsible for their administration. Our readers may remember a report which appeared in our issue of May 11th, 1907, p. 1311, of a conference of the United Children's Hospitals of London which dealt with this important matter, and we have now received from the Central Hospital Council for London the *and Physiology* into these two divisions, and hence that journal will continue to be issued as heretofore and the present part constitutes the second part of the forty-second volume. The contents of this part are: 1. The Comparative Anatomy, Gross and Minute, of the Thyroid and Parathyroid Glands in Mammals and Birds, by David Forsyth, M.D. Lond. In this research the first-mentioned glands obtained by careful dissection from 77 animals were submitted to microscopical inspection. The thyroid gland was found to be invariably present in mammals. Parathyroids are found in most, but not in all, members of the series. When present their total number is two, three, or four. 2. A note on the Development of the Septum Transversum and the Liver, by Peter Thompson, M.D. Vict. 3. The Brains of Aboriginal Natives of Australia in the Anatomy School, Cambridge University, by W. H. Duckworth, M.D., Part II., with 13 figures in the text, showing the sulci in different brains. 4. Studies in the Anatomy of the Pelvis, with special reference to the Fasciæ and Visceral Supports, by G. Elliot Smith, M.D., F.R.S. These studies are drawn from the examination of 20 adult subjects and a series of fœtuses and children, with many illustrations. The author accords high praise to Delbet's, Pasteau's, and Rieffel's contributions on this subject to the second edition of Poirier and Charpy's treatise on human anatomy. 5. An Unusual Duodenal Diverticulum, by Professor C. M. Jackson, M.S., M.D. 6. A case of Accessory Lobe of the Right Lung, by G. C. E. Simpson, M.B., B.Sc. 7. Further Observations on the Development of the Teeth of the Australian Aboriginal, by W. Ramsay Smith, M.D. Edin. 8. Note on a Tendon found in Association with the Insertion of the Peroneus Longus and Origin of the First Dorsal Interosseous Muscles, by Lieutenant-Colonel J. C. Lamont, I.M.S.

Revue de Psychiatrie, Nos. 9, 10, and 11, 1907.—The first of these numbers (No. 9) contains a report of the Congress of Alienists and Neurologists of France and the Latin Countries held at Geneva and Lausanne in August of last year. Dr. M. G. Ballet was the *rapporteur* on the subject of medico-legal evidence and the question of responsibility, and advances the thesis that the medical witness should confine himself solely to the diagnosis of disease and should not commit himself to the extent of the responsibility of the person on trial. In the subsequent discussion Dr. Grasset said that if responsibility was a function of the mind it might, in disease, be diminished or abolished and that the medical witness was competent to decide on the extent of the enfeeblement of that function. In a discussion on the *Periodic Psychoses* Dr. Régis avowed that he regarded the conception of maniaco-depressive insanity as subversive of the well-established classifications in so far as it suppressed the entities of idiopathic mania and melancholia. To justify the exclusion of these, the partisans of the maniaco-depressive theory find it necessary to sustain the proposition that cases of mania and melancholia always relapse, but this, according to Dr. Régis, is a simple affirmation which has nothing to support it. Dr. Ballet denied the existence of the simple non-relapsing forms but suggested the terms "excito-depressive" or "maniaco-melancholic" as being more appropriate than the present term. Dr. Schnyder, *rapporteur* on hysteria, desired to refuse to hysteria the characters of a clinical entity and to define it as a psychic modification in which there are an exaggeration and perversion of physical and psycho-physical reactions.—*No. 10* contains an interesting article by M. Lucien Picqué on Surgical Psychotherapy. The author divides the more severe psychoses which are liable to complicate surgery into those that are primary and undergo exacerbations with the occurrence of some bodily injury and those that are secondary to trauma either of some part of the nervous system or of some other part of the body. He indicates the importance of the part that psycho-therapeutics may play in the treatment of such psychoses and of the various forms of hypochondriasis that are so frequently met with in surgical practice. This number also contains an account of the proceedings of the Amsterdam Congress. —In No. 11 Dr. Damaye gives accounts of certain cases of Stupor and Mental Confusion in which the iodides appear to have been of therapeutic value. He suggests as a possible explanation of the benefits which appear to be derived from their administration that the mononuclear leucocytosis, which is at least sometimes coincidental with the taking of these salts, acts as a means of defence on the part of the organism against the toxins in the circulation.

The Liverpool Medico-Chirurgical Journal.—The January issue of this journal contains several papers of more than ordinary interest. Dr. Andrew Cassels Brown contributes an admirable account of the glimpses of medical matters at the time of the Wars of the Roses shown in the "Paston Letters." We commend it and the documents upon which it is founded to the attention of all medical antiquarians. Dr. Charles J. Macalister writes on the Personal Factor in Diet and points out that, although the physiologists may draw up ideal diet tables for the average man, actual individuals differ widely in their needs and idiosyncrasies as to food. On this ground are to be explained the theories set forth as to the advisability of mankind living on nuts, fruits, and so forth, which may suit some peculiar people. In the Surgical Section is a valuable article by Mr. F. T. Paul on his experience in abdominal surgery. The continuation of Mr. William Alexander's reports on Epilepsy presents some novel views on the treatment of this malady, and some interesting cases of disease of the gall-bladder are recorded by Mr. G. Reinhardt Anderson.

The Dublin Journal of Medical Science.—In the January number appears a paper by Sir John W. Moore, entitled "Diphtheritic Fever," in which are reported the notes of a series of cases of anomalous diphtherial infection without formation of false membrane. In most of the cases there was coryza with fever and the appearance of a rash, giving rise to a very puzzling clinical picture. Bacteriological examination proved the presence of somewhat attenuated Klebs-Löffler bacilli. Dr. Alfred de Roulet pleads for the treatment of many gynæcological conditions without recourse to operative measures.

The Birmingham Medical Review.—Two papers on Prevention of Disease appear in the December number of this journal, the first by Mr. J. Jameson Evans on Prophylaxis in Ophthalmology, which deals with a large number of different conditions, toxic and occupational, as well as infective; and the second, by Dr. John Robertson, on Prevention of Infective Disease. The latter writer notes the failure to prevent the occurrence of the commoner infections—measles, scarlet fever, and whooping-cough—due to the difficulty of recognising them at their very onset. Dr. James W. Russell records some cases of cerebral hæmorrhage occurring in connexion with acute endocarditis.

Guy's Hospital Gazette.—The issue of this journal of Jan. 25th contains some remarks made by Mr. R. Clement Lucas on Inherited Syphilis, in opening a discussion on this condition at a meeting of the Society for the Study of Disease in Children. Dr. H. C. Mann's observations on Arterial Blood Pressure in Health and Disease are continued, the present instalment being devoted to diseases of the heart.

The London Hospital Gazette.—The January number opens with a paper on Lupus Vulgaris of Mucous Membranes by Mr. H. Emlyn Jones, with some illustrations of the condition. Some Hints on Extraction of the Teeth are given by Mr. Frank M. Farmer. The Clinical Supplement is devoted to an article on Massage and Exercises in the treatment of surgical cases, and a short note signed "A. E." calls attention to a recently issued book by Mr. C. E. Walker on the gametoid

Annotations.

"*Ne quid nimis.*"

A WARNING TO PRACTITIONERS.

THE Registrar of the General Medical Council has addressed a circular letter in the following terms to the licensing bodies, teaching institutions, hospitals, infirmaries, and asylums in the United Kingdom, some 1500 in all:—

> It is very desirable that practitioners should not lose the privileges attaching to registration owing to their names ceasing to appear in the Medical Register. It has been found, however, that many practitioners, not fully appreciating this, especially within a short time of qualifying and registering, fail to give to this office from time to time an address at which official communications will reach them and they thus incur the risk of their names not being retained on the Register. In the interests, therefore, of the practitioners themselves the inclosed notice has been drawn up and I shall be greatly obliged if you will cause it to be displayed in a prominent place in your institution so that it may be brought to the attention of registered practitioners.
>
> Yours faithfully,
> H. E. ALLEN, Registrar.

The "enclosed notice" is a glazed card on which are printed the provisions of the Medical Act which enjoin registration on practitioners and rehearse the disabilities to which the disappearance of a name from the Medical Register renders its owner liable. All that is necessary for anyone to remember is to notify the registrar at the branch where registration was effected originally whenever a move is made which will be more than temporary. The chief offenders against this rule are probably young practitioners engaged in a series of resident hospital appointments. It is surely not much trouble to send a post-card when a change of appointment is made.

OFFICIAL ILLNESSES.

LEGISLATION has of late been busy with various forms of sickness or disease, when, that is to say, they affect employees. We are also promised a new and drastic Education Bill, but whether it will deal with the sicknesses to which teachers are liable is, of course, not yet known. The custom nowadays is to make it compulsory for the ratepayers to put their hands in their pockets for most expenses in education, and even where endowed schools exist there is a tendency "to improve" them out of existence. Our pious forefathers not only endowed schools for secular education but also provided for the teaching of religion, and, moreover, acting after that charity which the Apostle declared was the greatest of the three Christian virtues, made provision for the sickness of the teachers, or at least of one of them. Thus, we find in the statutes of "The School of St. Paul," founded by Colet in 1509, the following regulations as regards the Surmaister who was not, be it noted, the head or high master. "In sekenesse curable, as axis,[1] or suych other sekenesse for a time he shall be tollerated and have his full wagis." But the most remarkable statute is the following which shows a large-mindedness such as we doubt any educational authority would show now. "Yf after his commynge he fall sick into sickenes incurable, as Lepry, or Frenche Poxe, or after his long labour in the Scole fall into age ympotent, thenne I commit him to the charite of The Mercers, they of the cofer of the Scole to provide him a lyving as it may be possible, praying them to be charitable in that behalfe." Colet doubtless had a fellow feeling for those who were ill. The statutes for his school received their final shape in 1518 and in that same year he had his third attack of sweating sickness, of which there had been a severe epidemic in 1517. But it would be interesting to know why the "Surmaister" was allowed so much latitude in his ailments.

A ROYAL COMMISSION ON WHISKY.

WE note with satisfaction that a Royal Commission has been appointed to make inquiry upon the whisky question. The *personnel* is a strong one and includes the names of Lord James of Hereford (chairman); Mr. Laurence N. Guillemard, deputy chairman of the Board of Inland Revenue; Mr. Walter Adeney, D.Sc., F.C.S., of the Royal University of Ireland; Mr. J. Rose Bradford, M.D., D.Sc., F.R.S.; Mr. Horace T. Brown, LL.D., F.R.S.; Mr. George S. Buchanan, M.D., medical inspector and inspector of foods to the Local Government Board; Mr. John Y. Buchanan, F.R.S.; and Mr. Arthur R. Cushny, M.D., F.R.S. The terms of reference are:—

> 1. Whether, in the general interest of the consumer or in the interest of the public health or otherwise, it is desirable (*a*) To place restrictions upon the materials or the processes which may be used in the manufacture or preparation in the United Kingdom of Scotch whisky, Irish whisky, or any spirit to which the term whisky may be applied as a trade description; (*b*) to require declarations to be made as to the materials, processes of manufacture, or preparation or age of any such spirit; (*c*) to require a minimum period during which any such spirit should be matured in bond; and (*d*) to extend any requirements of the kind mentioned in the two sub-divisions immediately preceding to any such spirit imported into the United Kingdom.
>
> 2. By what means, if it be found desirable that any such restrictions, declarations, or period should be prescribed, a uniform practice in this respect may be satisfactorily secured. And to make the like inquiry and report as regards other kinds of potable spirits which are manufactured in or imported into the United Kingdom.

THE OFFER OF A RECEPTION HOSPITAL FOR ACUTE MENTAL DISEASES IN LONDON.

Dr. Henry Maudsley has made the munificent offer of £30,000 to the London County Council to provide a hospital the main objects of which shall be, in his own words: "(1) The early treatment of cases of acute mental disorder, with the view, as far as possible, to prevent the necessity of sending them to the county asylums; (2) to promote exact scientific research into the causes and pathology of insanity, with the hope that much may yet be done for its prevention and successful treatment; and (3) to serve as an educational institution in which medical students might obtain good clinical instruction." The letter containing the offer was read at the meeting of the council on Feb. 18th, the scheme having already been before the asylums, the finance, and the general purposes committees. The council passed a unanimous vote of thanks to Dr. Maudsley for his offer.

THE GERMICIDAL EFFICIENCY OF LIQUOR CRESOLIS COMPOSITUS.

A CORRESPONDENT writes: "In THE LANCET of August 24th, 1907, p. 544, it was shown that the liquor cresolis compositus of the United States Pharmacopœia was a more efficient germicide than carbolic acid. Another formula for this preparation is given in the German Pharmacopœia differing from the former in containing alcohol. Both contain 50 per cent. by weight of cresol or cresylic acid. The alcoholic preparation has been examined bacteriologically with favourable results by Mr. Ernest Quant.[1] Mr. Quant, adopting the Rideal-Walker method, determined the value of the preparation in terms of carbolic acid. In the case of bacillus typhosus he found that in a solution of 1 in 400 the cresol solution was equal in germicidal power to a 1 per cent. solution of pure carbolic acid. Further experiments were conducted with a 2 per cent. solution of the cresol solution to ascertain what length of time would be required for the destruction of active strains of typhoid and diphtheria bacilli. A series of exposures lasting from one to ten minutes, was made and in every instance the bacilli were killed, thus demonstrating that these organisms may be destroyed by exposure for one minute to a 2 per cent. solution of liquor cresolis compositus."

THE LANCET.

LONDON: SATURDAY, FEBRUARY 22, 1908.

The Sanitary Administration in India.

WE have been long accustomed to keep our readers informed of the progress of sanitary affairs in India and of the chief events in connexion with the work of the Indian Medical Service. The problems resulting from the consideration of these matters have grown greatly in importance during recent years, with the result that lately official opinion in India, and even to some extent in our own country, has been compelled to recognise their gravity, and indeed to consider them as amongst the most vital concerns of the administration of our great Eastern dependency. Truly vital are they in this, that on them hangs the life or death of hundreds of thousands of our fellow beings. Signs are not wanting that this has at last been driven home to the Indian bureaucracy and that it is setting itself seriously to work to promote the sanitary welfare of its country, and especially to combat that awful scourge which for over ten years has raged amongst the people whose destinies are in its keeping. In earnest of this we publish on another page a letter addressed some two months ago by the Secretary to the Home Department of the Government of India to all local governments and administrations under its control, stating its views on the subject of Sanitary Reform in India and asking for their advice and co-operation in the matter. Without considering them in detail at present we may say that the proposed plan seems to us to be laid on a broad and safe basis, but many important decisions must be come to before the best course is made manifest through a sea of conflicting perplexities. In calling attention to this new activity of the Indian Government it must not be considered that we think the sanitary administration in India has been neglected by the officers of the Indian Medical Service who are charged with its actual performance, for only recently we published a refutation of a shameless and anonymous calumny aimed against its members.[1] That service has a record for steady continuous hard work, conspicuous even in India, which has been served by its military and civil officials, working in many spheres and often under most arduous and disheartening conditions, with a loyal devotion of which any country might well be proud. But men, though they be as giants, cannot work miracles, and the task which to-day confronts the sanitary service in India is one with which its administration can hardly cope under present conditions. In support of this opinion the terrible plague problem comes at once to mind. We have dwelt on this matter often and it will be our duty to dwell on it, even to weariness, until by some means its ravages have been stayed. The last available reports received in this country state that from the beginning of last year to the end of October more than 1,100,000 deaths had occurred from plague in India. Plague has not left the country since its outbreak in 1895, and since that year has claimed at least 5,500,000 victims, the lowest yearly mortality during this century having been 274,000 in 1901. Chiefly on this account, but partly from other causes, the death-rate of all India has greatly increased since that year. To face this task we have urged that a special Plague Service is essential, for it is not within the power of the Indian Medical Service to stem that tide without well-organised assistance, however courageously it sets about doing so.

There are other factors which make the sanitary administration of India a task of increasing difficulty. Our methods of rule, including the very existence of that administration, have greatly increased the population with whose needs it must cope. In former days, moreover, we had to deal with enormous masses of people unversed in Western knowledge and ruled by feudal overlords whose education differed widely from our own. Now we have raised up a middle class of young Indians, highly trained in many directions, with a keen appreciation of modern scientific methods and with a growing influence on popular opinion in their country; these men cannot be dictated to on matters of science as though they were an ignorant peasantry, and though their support may be of the greatest value in the sanitary reformation of India, yet they must be honestly convinced of the soundness of our methods and not coerced into accepting them. As will be seen in the circular letter of the Indian Government, it proposes to open up the Sanitary Service as a useful and suitable career for this growing class. Whatever reforms are proposed in the direction of increasing the service, it must be remembered that before the country can derive the fullest advantage from its medical service there are certain grievances to the removal of which its officers are justly entitled and to which we have from time to time called attention, such as the period of their service, the multiplicity of their duties, and the limitation of the emoluments which they may derive from civil practice.

Being thus fully alive to the growing importance of this complex problem we intend to devote an increased amount of space to reports of Indian medical and sanitary affairs in future. We are enabled to do this largely by the courtesy of the governors, lieutenant-governors, and commissioners of the various provinces and the principals of the medical schools of the Indian Empire, who have consented to forward regularly to us the published reports dealing with these matters. Out of a very large pile of figures and facts we hope to present our readers with a digest which will fairly summarise the position of the many matters under the control of the Indian Medical Service, and the first of these articles is published in this issue. Amongst the subjects with which we shall deal will be the administration of hospitals, lunatic asylums, and gaols, the work of medical colleges, the progress of research in bacteriological and pathological laboratories, general sanitary administration, and the measures employed to suppress plague. We hope that of acetic acid. 4. That spirit vinegar should be vinegar obtained wholly by acetous fermentation of a dilute alcoholic liquor which has been obtained by distillation and contains not less than 4 per cent. of acetic acid. Similar definitions are suggested for wine vinegar, cider vinegar, and fancy vinegars. It is further suggested that a system of supervision over the vinegar factories should be organised, a system which would be welcomed by many vinegar makers as a necessary part of any proposal to require the nature of different vinegars to be stated to the public in terms which conform to prescribed definitions.

---

[1] THE LANCET, Jan. 4th, 1908, p. 37.

A CASE OF PAPILLOMA OF THE TRACHEA.

ALTHOUGH the trachea may be involved by growths in organs adjacent to it, such as malignant tumours of the œsophagus or of the thyroid body, primary growths of the trachea are of great rarity. Dr. M. Zondek of Berlin records an interesting case in the *Berliner Klinische Wochenschrift* of Feb. 3rd. The patient was a woman, aged 28 years, who for three years had suffered at intervals from soreness of the throat, cough, and difficulty in breathing, usually as a result of catarrhal attacks, to which she was very liable owing to her home being in a cold, damp, marshy district. She never complained of hoarseness at any time. About 15 months before admission to the Jewish Hospital in Berlin she began to suffer from persistent dyspnœa which gradually increased until she eventually had a severe asphyxial attack which lasted for some minutes and was only relieved after the expectoration of a considerable quantity of muco-purulent sputum. On admission the patient was pale, with cyanosed lips, and was breathing rapidly with marked inspiratory stridor. The muscles of the alæ nasi and of the neck were strongly contracted during inspiration but the larynx only moved slightly. The head was held forward and the chin was thrown upwards. The voice was clear and natural but speech was slow and interrupted. This position of the head and this manner of speaking both dated from childhood. On palpation of the trachea it was found to bulge forward slightly on the right side. The thyroid was not enlarged; there were no glandular enlargement and no difficulty in swallowing. The pupils were equal and reacted normally. On laryngoscopic examination a tumour with a rough surface was seen on the anterior wall of the trachea, on the right side just below the vocal cords which appeared to be natural. The tumour appeared to reach so far into the lumen of the larynx that only a small chink was seen between it and the left vocal cord; it did not, however, extend beyond the middle line and did not move either on respiration or phonation. There were no signs of syphilis or of tuberculosis. An endo-laryngeal operation was out of the question, so tracheotomy was performed. The thyroid body was pushed downwards. A large quantity of purulent material escaped from the tracheotomy wound which was then prolonged upwards to the cricoid cartilage. The tumour when exposed was found to be of the size of a walnut and its base of attachment was about the size of a sixpence, its upper margin being a thumb's breadth below the vocal cord. The consistence was soft and there was no infiltration of the surrounding mucous membrane. It was removed by means of a sharp spoon, together with a small part of the adjacent mucous membrane. There was very little bleeding. Recovery was rapid and uneventful. On microscopical examination the tumour proved to be a papilloma. About five months later the patient returned to the hospital and at the site of the operation a tumour of the size of a bean had appeared. This was removed, together with some mucous membrane, by Professor Israel after tracheo-cricotomy. About three years later the patient again suffered from the same symptoms at her home and died under anæsthesia during an operation. The interest of the case lies in its rarity and in the characteristic nature of the symptoms, demonstrating an obstructive condition of the main air passage not involving the cords. Owing to the peculiar carriage of the head and the interrupted speech Dr. Zondek is of opinion that the tumour originated in childhood. The condition is thus comparable to the laryngeal papillomata which occur in children.

THE REEK OF THE CIGAR.

SMOKING nowadays is commonly tolerated in the house, and even in the drawing-room a cigarette is sometimes permitted. The smoking of a cigar, pleasant though it may be to the smoker, and however irreproachable its quality, is banned by most careful housewives in their *sancta sanctorum* because its reek is so persistent. The stale smell of cigar smoke in a room is peculiarly unpleasant and peculiarly difficult to get rid of. It clings to the curtains and to most of the articles of furniture which present any sort of an absorbent surface. It is not so to the same extent with cigarettes or with pipes. In the case even of a single cigar books, papers, and textiles reek of its stale flavour and the room requires abundant airing before that flavour is completely eliminated. Air is an excellent scavenger but ozone is more active in removing the smell. The effect may be traced to the fact that the smoking of a cigar produces a larger quantity of pungent aromatic oils than does the smoking of a cigarette or pipe. In the case of the cigarette oils are probably burnt even if they are formed, in the pipe they condense in the stem, while in the case of the cigar they are probably for the most part discharged into the air. In the form of a cigar tobacco would appear to produce more oils than in the form of a cigarette or when burnt in a pipe. Such common observations are not without hygienic significance. Pyrridine, the most poisonous oil produced in the semi-combustion of tobacco, is an abundant product in cigar smoking, as it is also in the pipe, but in the latter there is condensation while in the former there is little or none. In the cigarette, so intimately in contact with the air is the burning portion that the production of distilled oils is, comparatively speaking, trifling. The symptoms of tobacco-smoke poisoning are not necessarily due to nicotine; they are more often due to pyrridine, or poisoning from tobacco tar oils. The tobacco heart is more often traceable to free indulgence in cigar smoking than to a similar indulgence in the pipe and the cigarette. Young boys can smoke—to their great damage, nevertheless—a considerable number of cigarettes or even pipes, but an equivalent in cigars more than satisfies their tobacco appetite so soon are the toxic effects of cigar smoking made apparent to them. The danger of excessive cigarette smoking is that though no marked symptoms may be manifested or experienced, yet in the long run decided harm is done and a dangerous habit, akin to "nipping," is cultivated which it is often found very hard to abandon.

HIRUDIN AND BLOOD GASES.

THAT the blood flowing from the bite of the leech does not coagulate has long been known and has been attributed to the action of a material secreted by the salivary glands of that animal. The advantages which it offers in the investigation of the gaseous exchange of the organs of the body by preventing clotting are obvious and have recently been made the subject of a research (recorded in the *Journal of Physiology*) by Mr. J. Barcroft and Mr. G. R. Mines who have set themselves the task of determining whether it produces any alteration in the gases of the blood. The quantity of the active principle, hirudin, prepared for them in Leipsic, which they injected was 0·2 gramme report of a committee appointed by the Council in last July to consider a reference in the following terms—namely, "Whether the London hospitals should be advised to take joint action with a view to insuring the purity of their milk-supply." The committee has had the advantage of very expert evidence in its deliberations, as it consulted several large distributors of milk on the one hand and medical officers of health and analysts on the other. It finds that the practice at present prevailing in 12 hospitals is to require from the milk contractors certain percentages of total solids and fat in the milk supplied; one hospital has no form of milk tender at all, whilst eight, in addition to the percentages, require the notification of the farms of supply and also the periodical certification of the health of the cows from which their milk is derived. The committee recommends the constituent hospitals of the council, which represents all the larger London hospitals, to require their respective contractors to agree to the following conditions which it is advised are fair and reasonable :—

1. That the milk shall be pure, genuine, with all its cream as yielded by the cow, absolutely free from any and every kind of adulteration (including preservatives), and shall be of such quality as will, between the months of August and January, both inclusive, produce at least 3·5 per cent. of butter fat, and for the remainder of the year 3·25 per cent. of butter fat.

2. That the milk shall be supplied from a farm or farms whose name or names and locality are to be notified by the contractor to the hospital.

3. That it shall be permissible for an authorised representative of the hospital to visit and inspect such farm or farms and the herds there at any reasonable times.

4. That the cows supplying the milk shall be in a good state of health and that the contractor shall give the hospital a certificate by a veterinary surgeon to that effect in the annexed form* without cost to the hospital in the first instance, and shall give subsequent certificates whenever required by the hospital at the hospital's expense.

5. That the milk shall be strained and cooled to the temperature of cold water, not exceeding 60 degrees, at the farm, and there canned and sealed with a die to be supplied by the hospital, and that all cans shall be dust and rain-proof.

6. That the contractors shall guarantee the cleanliness of the milking operation and of the men's hands and of all receptacles into which the milk is put, all of which receptacles shall be properly cleansed with a solution of boiling water and soda.

7. That the cans shall not be opened in transit except at the London railway station by the public sanitary inspectors and if so opened shall be immediately re-sealed for delivery to the hospital and shall in every case be delivered direct from the London railway station to the hospital.

8. That the milk shall not be pasteurised or treated otherwise than as mentioned in Clause 5 without the written sanction of the hospital authorities.

The percentage of butter fat insisted on is rather above the average amount found in London milk and even above that yielded by many cows, but it must be remembered that for most of the children in the hospitals and for many of the acutely ill, especially in such cases as those affected with enteric fever, milk forms the staple of the diet, and therefore milk of quality above the average is not unreasonable. The last section of the report recommends certain precautions outside the contracts to be observed by the hospitals, the chief of which is the securing of the coöperation of the medical officers of health of the districts in which the farms are situated in supplying reports of their sanitation and the freedom from infectious disease of their employees. It advises at least one weekly analysis of the milk, made on irregular days, and suggests the joint employment by a group of hospitals of an inspector to visit the farms. It is further suggested that the contracts should be framed with a summer and winter price for the milk instead of with an average all the year round price. The committee is of opinion that in view of the serious interests involved the risk of a slight increase in price which these more strict conditions will entail may be justifiably incurred, and with this opinion we are in complete concord. The committee has been well advised to make its conditions such that any well-equipped farm can reasonably comply with them. The aim in the imposing of the above conditions has been to insure not merely the delivery of milk of a high quality as regards the percentage of its important constituents but also the absence of harmful substances, whether accidentally present or added with a view of preventing decomposition. It will be noticed that no bacteriological test is suggested; the reason for this omission is that the committee recognised the difficulty of applying any such test; the avoidance of the presence of harmful micro-organisms must be insured, not by occasionally looking for them in the milk but by the maintenance of hygienic conditions in the farms whence the milk comes and amongst those engaged in the milking.

It is, however, not enough to lay down elaborate conditions under which the milk is to be produced and delivered; it is essential that by inspection the maintenance of these conditions should be assured. One of the constituent hospitals has for several years required that the farms whence its milk comes shall be liable to inspection by a representative from the hospital, but on no single occasion has any farm been visited. It is very harmful to lay down stringent conditions without taking care that these conditions are maintained, and it may well be that worse milk is supplied than if no conditions had been imposed, for the more conscientious milk providers will gradually be shut out and will cease to tender. For if a milk provider knows that the conditions will never be enforced, and if he be not perfectly scrupulous he will be able to underbid those who fully intend to carry out the letter of their tenders, and therefore the milk supplied will be worse than the conditions imply. It is of the first importance, therefore, that any condition inserted in a tender should be enforced by the hospital authorities and this requires not only that the milk supplied should be periodically tested at the hospital but also that the farms, the cows, and the *personnel* of the farms should be periodically inspected. An individual hospital could not afford to employ regularly an inspector, but if all the hospitals in London were to combine the cost of inspection need not be great. The visits must be fairly frequent and at irregular intervals if they are to be really useful. It is possible that the Central Hospital Council might serve to organise such an inspection. The quantity of milk consumed by the hospitals in London must be so enormous that they should be able to carry out great reforms in the methods of production and supply of milk, and indirectly to improve the quality of the milk obtained by London.

WESTON-SUPER-MARE HOSPITAL.—On Jan. 21st a ward containing a single bed was formally opened at this hospital by the Rev. Prebendary Salis in the presence of a large gathering. The ward is called the "Poole Ward," as the late Mr. E. Poole bequeathed £1200 to endow the bed.

---

* This paper contains a form for the veterinary surgeon's report on the cows, an undertaking to be signed by the contractor not to supply milk from any animal found to be diseased, and on the back a blank form for the description of the disease of such animals and of their treatment.

is of the sclerous type, i.e., of slow evolution and compatible with prolonged survival. In the words of Professor Landouzy, "The little finger of a patient tells his past, shows his temperament, and foretells his future."

PLAGUE ON THE GOLD COAST.

IN another column of this issue there will be found an advertisement from the Colonial Office stating that six medical men are wanted for plague duty on the Gold Coast. The terms as tersely put in the advertisment are, "six months' engagement, free passages to and fro, travelling expenses paid, camp equipment and tents provided; pay £50 a month," while experience in plague duty is naturally desired. The forms of application may be obtained before March 7th from the Assistant Private Secretary, Colonial Office, Downing-street, S.W. The decision of the Government to send extra medical help to the Gold Coast must not be taken to indicate that the outbreak has reached alarming dimensions. On the contrary, with the exception of a few cases at a small coast town called Brewa, the disease is still confined to Accra where it began early in January. The latest reports give a mortality of one, two, and three a day, and since the beginning the mortality has never exceeded six in one day. As has been already announced in our columns, Professor W. J. R. Simpson, M.D., was despatched to Accra with an assistant at the beginning of the year, and very energetic measures have been taken; but the available medical staff is felt not to be sufficient to enable a close watch to be kept over the various towns on the coast which are at present free from infection, but where, as a measure of precaution, it is very desirable to have competent observers stationed so as to detect at the outset any cases or suspected cases of plague. Hence the demand for special officers is a valuable preventive measure, and we trust that the Government will have no difficulty in obtaining what is sought.

DEAR BUTTER.

THE substantial advance in the price of pure butter will come as a hardship to many families. Accounts are more or less conflicting as to the causes which have led to the increased price, but two factors have been mentioned as responsible, one of which is a shortage in the supply, and the other fresh legislation in regard to the sale of butter substitutes. We are inclined to attribute the rise in price entirely to the new Butter and Margarine Act which came into force on the first day of this year. If we are right in this view, then the conclusion is inevitable that enormous quantities of foreign fat have been sold in the past as genuine butter. The new Act, in short, is the death-blow to this dealing, and the fact that the supply of genuine butter has become short is significant. The effect should be a great stimulus to the genuine butter industry and we have little doubt that the demand for genuine butter will be more than adequately met as the position is accepted. Meanwhile the public need not suffer any shortage in regard to that most important element in diet, namely, fat. It may be true that genuine butter fat is the most digestible of all fats, but there can be little doubt that many of the substitutes are nearly if not quite as good in this respect. Margarine, cotton-seed and other vegetable oils, and dripping are perfectly wholesome and palatable substances and afford good human food. It is no argument against their use for dietetic purposes that certain of them have been employed wherewith to adulterate butter. The question never has been that these substitutes were injurious or unfit for food; it was purely one of misrepresentation. They were sold entirely or in part as butter when they were not butter, and that fact alone has created a prejudice against them as articles of food—a prejudice which we hope will disappear now that the sale of the genuine article has been placed on a satisfactory basis. We welcome this new Act because it is an Act calculated to make things what they seem, and the present dear price of genuine butter will, we are inclined to think, be only temporary.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

H.R.H. the Prince of Wales, at the suggestion of the Executive Committee of King Edward's Hospital Fund for London, has decided to appoint a committee to inquire into the system prevailing in the London voluntary hospitals with regard to the admission of out-patients. We learn this fact with pleasure, for provided that the committee be well chosen its pronouncement upon the best way of dealing with the acknowledged troubles of hospital abuse might be regarded in some sort as authoritative. The evils of hospital abuse are many and are not apparently on the decrease, but great difference of opinion exists, even among those who have studied the problems most closely, as to the direction in which remedy should be sought, this difference being equally present whether the right of the sick poor or the wrongs of the exploited medical profession are under consideration. We are informed that in view of the fact that some portion of the subject of inquiry by such a committee would probably fall within the subjects to be reported upon by the Royal Commission on the Poor-laws the committee will not be appointed until that Commission has reported.

The Department of Public Health of Queensland, in a bulletin dated Jan. 11th, states that no case of plague in man has occurred since Jan. 1st. The Acting Governor of the Gold Coast, in a telegram received at the Colonial Office on Feb. 13th, states that the total number of deaths from plague at Accra for the three days ending Feb. 12th were 5. The new cases numbered 6. Further telegrams received respectively on Feb. 14th and 15th state that 1 death occurred from plague at Accra on Feb. 13th and 1 on Feb. 14th. No fresh cases had been notified.

AS we have already announced, the 135th anniversary dinner of the Medical Society of London will take place at the Whitehall Rooms, Hôtel Métropole, London, on March 11th, under the chairmanship of the President of the society, Dr. J. Kingston Fowler. Applications for tickets should be made to the honorary secretaries, Dr. F. J. Poynton and Mr. T. H. Kellock, 11, Chandos-street, Cavendish-square, W.

FAVOURED for the greater part of his short visit with good weather for the time of year, His Majesty the King derived great benefit from his week's stay at Brighton. His Majesty's personal assurance that he had benefited by his stay has been made public, as well as his hope to pay another visit to Brighton.

Mr. Charters J. Symonds delivered the second Lettsomian Lecture for 1908 before the Medical Society of London on Feb. 17th, the President, Dr. J. K. Fowler, being in the chair. This lecture will be published in THE LANCET in a future issue.

CREMATORIUM FOR ST. PETERSBURG.—The president of the sanitary committee has submitted his report to the St. Petersburg town council in favour of the establishment of a crematorium in the town to be used with due regard to the interests of justice and in fulfilment only of the testamentary instructions of such deceased persons as may have decided to be cremated.

* No trustworthy average.

† This rainfall is for Leith.

The figures above represent the number of hours of bright sunshine, the number of days with rain (at least 0·01 inch), and the aggregate fall for 1907. All the figures have been published by the Meteorological Office and the sunshine values have been obtained by the burning recorder known as the Campbell-Stokes instrument. Along the east coast the sunniest spot was Skegness with 1739 hours, followed closely by Clacton-on-Sea, Felixstowe, and Lowestoft; and on the south coast the brightest resort was Eastbourne, with an aggregate of 1848 hours. This resort was, with the exception of Guernsey, the sunniest place in the Kingdom, although Jersey, Bognor, and Hastings were not far behind. In the south-west of England none of the resorts equalled Torquay with its total of 1739 hours, while in the north-west the brightest place was Rhyl with 1640 hours. Among the inland localities the brightest was Bath, with 1674 sunny hours, followed by Tunbridge Wells with 1635 hours, while the dullest was Manchester, with no more than 894 hours. In the metropolitan district Kew received about three-quarters of an hour per day more sunshine than the City, but the City station, Bunhill-row, had more than three quarters of an hour per day more than Manchester. The mean daily difference between the City and Eastbourne was nearly two hours, while the mean difference between the two extremes, Eastbourne and Manchester, exceeded two and a half hours per day. It will be seen that most places in the south-west, and also those in Ireland, had less sunshine than usual, and that the greatest plus differences from the average were at Blackpool and Eastbourne. Referring to the rainfall it will be observed that Clacton-on-Sea was the driest place, with less than 17 inches of rain, and that inland the driest place was Westminster, where the total was 19·5 inches. Over the country as a whole the rainfall was almost identical with the normal, but most places in the south and east were drier than during an average year.

WHAT IS VINEGAR?

SOME interesting information on the preparation and sale of vinegar in relation to the administration of the Sale of Food and Drugs Acts is contained in a recently issued report to the Local Government Board by Dr. J. M. Hamill. It appears that various questions relating to alleged adulteration and misdescription of vinegar have been brought to the notice of the Board from time to time by vinegar manufacturers, public analysts, and others. Dr. Hamill in the course of his inquiry has visited the works of some 20 important firms of vinegar makers in London and the provinces and also those of smaller manufacturers of different kinds of vinegar. He has also gained information from public analysts, chemical advisers of vinegar brewers, acetic acid importers, and others. The view of many vinegar makers and public analysts is that a set of official definitions is demanded, and the following suggestions are made: 1. That vinegar or brewed vinegar should be a product obtained wholly by the alcoholic and subsequent acetous fermentation of a saccharine fluid obtained from malted barley, unmalted cereals, grain, or sugar, and should contain not less than 4 per cent. of acetic acid (in malt vinegar, in addition, the saccharine fluid should be obtained either wholly from barley malt or from a mixture of malted and unmalted barley, together with such proportions of additional substances as may from time to time be permitted by official regulation). 2. That artificial vinegar should be any vinegar or substitute for vinegar containing any added acetic acid which is not wholly the product of alcoholic and subsequent acetous fermentation and should contain not less than 4 per cent. of acetic acid. 3. That distilled vinegar and distilled artificial vinegar should be respectively the products of distillation of vinegar and artificial vinegar and contain not less than 4 per cent.

From this examination there were certain indirect results that are worthy of note. For instance, we learn that children, not necessarily consumptive, were found to be suffering from physical defects which either interfered with school progress or were likely seriously to influence the future life of the children, and for these medical treatment was enjoined. Many cases of heart trouble, greatly enlarged tonsils or adenoids, and carious teeth were thus detected and placed under treatment. As to the actual returns respecting the two schools above specified, out of 1670 children examined, signs in the lungs that would justify a diagnosis of tuberculosis were found in *eight cases only*. In 14 other children slight signs were found—prolonged expiratory breath sounds, or dry fine crepitation at the margin of the lungs—which might possibly be due to tuberculous infection. Even if these are included as actual cases of tuberculous disease, the percentage of possible pulmonary tuberculosis reaches only 1·3 per cent. There is a further small proportion in which enlarged veins on the chest suggest the possibility of enlargement of bronchial glands due to tuberculous changes, but without any evident lung affection. Nearly three-fourths of the children examined presented enlargement of the cervical lymphatics and over 40 per cent. had enlarged tonsils.

Within the administrative County of London there are at the present time 23 invalid schools containing about 1800 physically defective children. These children are daily conveyed to and from school in 35 ambulances and 11 omnibuses, and their conveyance to school as well as their care there are provided for by the employment of 24 nurses. The admission of an invalid or crippled child to these schools is permitted only after medical examination. In most cases the decision as to whether or not a child is fit for admission is an easy matter. But there is clearly an advantage in securing for special cases the opinion of an expert surgeon. It is necessary to have regard to the possible future of the child in each particular case. Some children would be the better for gentle exercise or work suited to their strength, whilst for others absolute rest is a necessity. During the past year Mr. R. C. Elmslie has carefully examined every case on admission to school with manifest advantage to the children under his care. He has examined more than a thousand children in 15 "physically defective" centres, and has noted in each case the nature of the disease or defect, the prevalence of active disease or of deformity, and the efficiency of any treatment adopted. Of these cases in the aggregate 80 per cent. began before the age of seven years and 67 per cent. below five. Of the spinal cases 72 per cent. occurred before the fifth year of life, whilst of the hip cases 64 per cent. occurred between the ages of two years and six. In the large majority of cases of tuberculous disease of the spine the onset of the disease occurs quite early in life, somewhere between the second and the fifth year. Tuberculous disease of the hip-joint is evident at a somewhat later age than spinal caries. The age distribution of tuberculous disease of the knee-joint is much more even than that of the two preceding forms of infection, the disease appearing for the most part about equally in each year of the first nine. Of the 83 cases observed two were bilateral, in 27 of which the disease was active and in 54 inactive. Very interesting particulars are given of the results of tuberculous bone disease, as regards deformity, crippling, &c., but for these reference must be made to the report itself.

SANITARY REFORM IN INDIA.

I.

AN important letter has been recently addressed by the Secretary to the Government of India, Home Department, to all local governments and administrations upon the subject of sanitary reform. We reproduce it verbatim and hope that our readers will appreciate the fact that a grand effort is now being made to improve the public health of our enormous Eastern Empire:—

1. I am directed to address you on the important subject of the improvement of the sanitary services in India and the development of the present establishment on lines which will bring it abreast of modern requirements.

2. The history of sanitary administration in India was reviewed in the Home Department Resolution of Sept. 8th, 1904, in which the appointment of a Sanitary Commissioner with the Government of India was announced. That resolution concluded with the expression of a hope that, with the assistance of the Sanitary Commissioner's advice and in consultation with local governments, substantial progress might in the course of time be made towards a complete reorganisation of the Sanitary Department. The Governor-General in Council is of the opinion that the time has come when an endeavour may be made to realise expectations and I am accordingly directed to offer for consideration the following suggestions regarding the nature and direction of the advance which should now be made.

3. The administrative machinery of the sanitary department is already, in most respects, fairly complete and efficient. Additional deputy sanitary commissioners are probably needed in some provinces, and I am desired to request that the question of increasing their numbers may be borne in mind. These officers are at present recruited *solely* from the Indian Medical Service, and though that arrangement must probably continue for some little time, the Government of India are disposed to think that the appointment should not be reserved exclusively for officers of that service, but should be open also to the medical officers of health referred to below. And they are further of the opinion that no officer of the Indian Medical Service should be appointed a deputy sanitary commissioner, unless he is of less than seven years' service and has secured a degree or diploma in public health. The latter condition would be applied to all candidates whether members of the Indian Medical Service or not.

Sanitary Boards.

4. Another part of the administrative machinery which has been developed in different degrees and has attained positions of varying usefulness in different provinces is the Sanitary Board. The Government of India believe that these boards are beneficial in emphasising the importance of the subject of sanitation, in correlating sanitary schemes with administrative exigencies, and in securing direct discussion between sanitary experts and those who are in a position to appreciate and represent the attitude of the general population. They are disposed to think that the Board should consist of from three to five members, including a senior officer of the Civil Service, who is in close touch with the local administration, the sanitary commissioner, and the sanitary engineer as experts, and one or two natives of India, preferably non-officials. If the chief engineer and the head of the Provincial Medical Service are placed on the board the local government is deprived of the independent expert advice which it requires when dealing with the board's recommendations. The functions of these boards have hitherto been mainly advisory, but it is possible that they might be so constituted as to be able to relieve local governments of much work of minor importance. I am directed to suggest that the question of the constitution and powers of the sanitary board should be examined and to request that the Government of India may be favoured with your opinion and proposals upon this question.

Medical Officers of Health.

5. Turning now to the executive establishment the first defect that forces itself upon the attention is the inadequacy of the staff of medical officers of health. The Presidency towns and a few other cities have such officers, but speaking generally the civil surgeon is the only health officer of the towns in a district. It is often difficult for him to give sufficient attention to the sanitary requirements even of the headquarters town. It is quite impossible for him to do more than make an occasional inspection of other towns. A complete and qualified staff of sanitary experts is a necessary preliminary to any substantial improvement of sanitation. If reforms are to be planned on right lines and carried out with efficiency and economy the work cannot be left in the hands of officers who have only a general knowledge of the subject and whose time is largely occupied by other duties.

6. The Indian Plague Commission of 1900 recommended that a special European medical officer of health should be attached to every town which contains a population of 100,000 inhabitants, and that one European assistant health officer should be provided for each additional 100,000 inhabitants. The Government of India consider that the standard of population suggested is reasonable and moderate. They are of opinion, however, that it is unnecessary and even inexpedient to require that all these health officers should be Europeans. A sanitary service offers a suitable and

for every five kilogrammes of body-weight of the animal, the strength of the solution being about 1 per cent. It was found in some preliminary experiments that hirudin has no specific effect on the gases in drawn blood. When subcutaneously injected it was found that the oxygen in the arterial blood rose to a variable extent whilst the carbonic acid fell. The respiration was quickened, an effect that followed quickly upon a considerable fall in the blood pressure. The fall in blood pressure is consequent upon dilatation of the peripheral vessels in the visceral area and presumably elsewhere. Cerebral anæmia is thereby caused and consequently increased respiration. The increased respiration decreases the amount of carbonic acid in the blood to a slight extent and tends also to increase the oxygen. If hirudin be injected too rapidly death may occur.

THE LATE DR. W. S. PLAYFAIR.

THE sum of £1000 has been collected among the patients and friends of the late Dr. W. S. Playfair and is to be presented to King's College Hospital with a view to erect a memorial to him at the institution with which he was so long associated. In view of the eminent services rendered to the hospital in the past by Dr. Playfair, and in deference to the wishes of his family, it has been decided by the removal fund committee to devote this money to the building and equipment of an appropriate department of the new hospital shortly to be erected at Denmark-hill, this department to be named after him and to bear an inscription recording his 35 years' work at King's College Hospital.

A DEPILATORY FOR USE BEFORE SURGICAL OPERATIONS.

IN the *Journal de Médecine et de Chirurgie Pratiques* a formula is given for preparing a depilatory for use before operations. It consists of sodium monosulphide, 1 part; calcium oxide, 1 part; starch, 2 parts; and sufficient water to form a stiff paste. The longer hairs are removed with scissors and then, after washing the patient thoroughly, the paste is spread in a uniform layer with a spatula. After five minutes the paste is removed by means of a sterile swab of cotton and the skin is washed freely with sterile water to remove the alkali.

THE LOCKING OF MILK CHURNS.

THE proposal of the London County Council in a clause in its General Powers Bill to examine samples of milk at railway stations in its area is to be petitioned against by the East Sussex County Council. The London authority is anxious to trace the origin of any unwholesome milk that may arrive in the metropolis but the rural authority objects to the proposed power on the score of the possible hardship to the farmer. Many hours frequently elapse from the time when the farmer places the milk in a train at a country railway station and its process of being doled out at one of the London termini. Is the farmer to be responsible for the milk in the interim? The East Sussex County Council at its meeting on Feb. 11th replied in the negative. It asks that the particular clause may be amended by providing that the person producing or consigning the milk shall not be liable if he can prove that the milk contained no matter rendering it unwholesome or unfit for the food of man when so produced or consigned. To some extent the object of the farmer could be surmounted by the lids of the churns being locked during transit. This would prevent any possible tampering either during the railway journey or on the platform at any station, except by some authorised person. The general practice, as was pointed out over and over again in a series of articles which appeared last year in our columns dealing with the subject of the railway transport of milk to London, is not to lock up the churns: the contents are accessible to anyone—and anything that comes along. Of course, locking the churns would not obviate the harm that may occur through delay in transit, but it would stop much gross defilement.

"CAMPTODACTYLIA."

IN a clinical lecture delivered at the Charité Hospital in 1885 and in an article which appeared in the *Presse Médicale* of April 21st, 1906, Professor Landouzy has described under the name of "camptodactylie" (καμπτός, bent, and δάκτυλος, finger) a condition of permanent and irreducible inflexibility of one or several fingers which develops gradually without pain or inflammation and affects only the interphalangeal joints, never the metacarpo-phalangeal. The palmar fascia is intact and the ends of the bones do not present nodosities. At a meeting of the Société Médicale des Hôpitaux of Paris on Jan. 10th M. Ch. Lesieur read an important paper on camptodactylia which, he said, might be unilateral or bilateral. When unilateral the right hand is the more frequently affected; when bilateral the condition most frequently commences in this hand and predominates there. Usually only one finger is affected, even in the bilateral form, and that finger is nearly always the little one. When more than one finger are affected the fingers involved are the little and ring, sometimes the little, ring, and middle fingers; the index participates only exceptionally. When several fingers are involved the little finger is always the most affected, the ring finger less, and the middle finger least. Each affected finger may be inflexible at one interphalangeal joint or at both joints. In the first case the deformity forms a more or less obtuse angle; in the second the finger has the aspect of a hook formed by a line broken at two points corresponding to the joints. It also may happen that the second phalanx is flexed on the first and the third extended on the second. A pathognomonic characteristic of camptodactylia is its irreducibility: extension of the finger is limited by the degree of the deformity and the impression is given of tension of the flexor tendon. On the other hand, there is no obstacle to flexion, and in some cases this movement shows adhesion of the retracted tendon to the overlying skin. Even when marked, camptodactylia does not interfere with the use of the hand. Professor Landouzy regards camptodactylia as a stigma of "neuro-arthritism" and due to some functional disturbance at the confines of the cervical and dorsal region of the spinal cord. But M. Lesieur thinks that the condition has some causal relation to tuberculosis for the following reasons: Camptodactylia resembles the retraction of the tendo Achillis which has been observed in tuberculous ulcers of the leg. In the condition termed by French writers "tuberculous abarticular rheumatism" fibrous tissue is involved. Finally, camptodactylia clinically resembles contraction of the palmar fascia, which some French writers regard as tuberculous. M. Lesieur therefore investigated 100 cases of camptodactylia. In these 87 of the patients were avowedly tuberculous, seven probably tuberculous, and six appeared to be free from the disease. But of the last group several gave a family history of tuberculosis and the greater number showed slight lesions, such as acrocyanosis which is regarded as a tuberculide. In the 87 cases of avowed tuberculosis the lungs were affected in 78, the lymphatic glands in 23, and the bones in seven. In most of the tuberculous cases the lesions were of attenuated virulence, with a tendency to sclerosis, progressing for the most part towards cure or even already cured. Thus camptodactylia is of great use both in diagnosis and prognosis of tuberculosis. It is possible to say that a patient is tuberculous simply by examination of his fingers, for camptodactylia is a stigma of tuberculosis. In prognosis it is equally useful; it shows that the tuberculosis and festivals. Their services would further be valuable in connexion with measures against plague and other epidemics. If a supply of trained men is brought into existence local bodies should be encouraged to avail themselves of it for services of this nature, but in most provinces it is probably undesirable to go farther than to require that where sanitary inspectors are employed none but trained men should be appointed.

Sanitary Engineers.

13. The question of providing an efficient staff of sanitary engineers has been engaging the attention of the Government of India for some time and the conclusions at which they have arrived will be announced in a separate communication. The matter is mentioned here only in order to give an assurance that its great importance in connexion with the subject of sanitary advancement has not been overlooked.

14. I am directed, in conclusion, to request that the various suggestions which have been put forward in this letter may be considered and that after consulting such official and non-official opinion as may seem desirable you will favour the Government of India with an expression of your views upon the whole subject. The Government of India would like at the same time to learn what specific action you propose to take in order to give effect to the accepted policy of sanitary improvement.

Postscript (to Madras only).—The Governor-General in Council is aware that there already exists in Madras a body of trained sanitary inspectors and that rules regarding their employment and remuneration have been issued by the local Government. Much of the foregoing discussion of this subject is, therefore, inapplicable to the circumstances of that Presidency. On the other hand, the experience gained there will be valuable in dealing with the questions under consideration and the Government of India hope that the Governor in Council will favour them with an account of the Madras system, together with his opinion on the value of the results obtained and the direction in which amendment may be desirable.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Feb. 13th, MR. HENRY MORRIS, the President, being in the chair.

The SECRETARY reported the death of Mr. William Allingham, past member of the Council. The following motion was carried:—

That the Council hereby express their sincere regret at the death of Mr. William Allingham and their sympathy with the members of his family. The Council do also record their appreciation of Mr. Allingham's services to the College while Member of Council and their regard for the skill and ability which won for him a prominent position among the surgeons of the time.

It was resolved to issue diplomas of Membership to 66 successful candidates. It was also resolved to issue, in conjunction with the Royal College of Physicians of London, diplomas in Public Health to 12 successful candidates.

The Council then proceeded to the election of the Conservator of the Museum, and from the candidates, all of whom were zoologists, the Council selected Mr. Arthur Keith, M.D. Aberd., F.R.C.S. Eng., lecturer on anatomy and Curator of the Museum at the London Hospital Medical School.

At the last annual meeting of Fellows and Members the following motion was carried:—

That the President and Council of the Royal College of Surgeons be asked to use their moral influence with hospital authorities to recognise Members of the College (who are also in almost all cases Licentiates of the Royal College of Physicians) as having equal rights with Provincial, Scotch, and Irish graduates to become candidates for hospital appointments.

In accordance with the report of the committee which had been considering this resolution the Council decided to send the following memorandum to the hospitals in England and Wales:—

Attention having been called to a regulation in force at some hospitals, under which the ordinary pass degree of any British University is accepted as qualifying for appointments on the staff, whereas the diplomas of *M.R.C.S. Eng.* and *L.R.C.P. Lond.* are not so accepted, the Council of the Royal College of Surgeons of England desire to point out the injustice of this regulation to Diplomates of the two Royal Colleges. In the first place the Council would call attention to the fact that since the introduction of the five years' curriculum the course of professional study required at the universities has not been longer than that required by the Colleges. Moreover, statistics recently compiled by a committee of the General Medical Council show that the average course of study in England is longer than that in Scotland or Ireland, and the inference is drawn by the committee that this difference is due to the regulation of the Royal Colleges in England which guarantees for the subjects of the final examination an uninterrupted period of study of two years from the date of the completion of the intermediate examination.

With regard to the standard of examination, the Council maintain that the examinations in professional subjects, which candidates for the diplomas of the Royal Colleges in England are required to pass, are not less exacting than those required for the pass degrees of most universities. In support of this contention the Council would point to the marked success of the diplomates of the Royal Colleges in England at the examinations for the Royal Navy Medical Service, the Royal Army Medical Corps, and the Indian Medical Service. (See below.)

The Council believe that, in many cases, the regulation in question was made at a time when there were not more than four universities in England, and when the conditions for obtaining the degrees of those universities were in some respects more exacting than those imposed upon candidates *for the diplomas of the two Royal* Colleges; but, having regard to existing conditions, they are of opinion that, in all cases in which those holding only the pass degree of a university are accepted as eligible for staff appointments, the same privilege should be accorded to those who hold the diplomas of *M.R.C.S. Eng. and L.R.C.P. Lond.*

The Council therefore trust that the authorities of hospitals in England and Wales, who make this distinction between diplomates and graduates, will see their way to modify a regulation which affects unjustly many who have studied and qualified in London, where the clinical advantages for medical and surgical education are unsurpassed and places them at a disadvantage with those who have graduated in Scotland, Ireland, and elsewhere.

Analysis of Returns as to the Examinations for the Medical Department of the Royal Navy, the Royal Army Medical Corps and the Indian Medical Service during the five years 1903-07, compiled from Tables presented to the General Medical Council.

	Passed.	Re-jected.	Per-centage passed.
M.R.C.S. Eng. L.R.C.P. Lond.	344	32	91·5
English University Graduates	103	12	89·5
Irish University Graduates	153	25	85·9
Scottish University Graduates	162	40	80·1
L.S.A. Lond.	14	5	73·6
Indian and Colonial University Graduates	16	9	64·0
Irish Conjoint Diplomates	76	46	62·2
Scottish Conjoint Diplomates	50	42	54·3

The foregoing statistics are compiled from the results of 27 examinations, and the high position in order of merit obtained by the diplomates of the two English Royal Colleges is shown by the following table:—

First place gained by	M.R.C.S. Eng. L.R.C.P. Lond.	18 times in 27 examinations
Second	" "	20 " " "
Third	" "	14 " " "
Fourth	" "	15 " " "
Fifth	" "	16 " " "

It was resolved that the Royal College of Physicians be informed that the Council is preparing to issue a circular to Fellows and Members of the Royal College of Surgeons of England asking their opinion as to whether or not it is desirable that women should be admitted to examination for the diplomas of the College, and that pending the result of this inquiry it is not proposed by the Council to take any further steps with regard to the petition from the London School of Medicine for Women. The following is the circular to the Fellows and Members:—

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

DEAR SIR,—The Council, although they have decided that it is desirable to admit women to examination for the Diploma of Member, and although they have power to act upon this opinion, are anxious, in accordance with a resolution passed at a meeting of the Council on May 9th, 1907, to obtain the views of the Fellows and Members on the matter.

In regard to the corporate position of women if the diplomas of the College be granted to them, the Council have taken legal opinion and are advised that, while under the Medical Act of 1876 (39 & 40 Vict. Ch. 41) women can be admitted as Members or as Fellows, no woman so admitted would thereby be entitled to take any part in the government, management, or proceedings of the College.

It is hoped that you will answer the questions on the accompanying post card, and return the card at your early convenience. In order to give time for the arrival of replies from the colonies and other distant localities, the poll will be kept open until the day of , 1908.

Voting Card.

	Answer.
A. In your opinion is it desirable that women should be admitted by examination as Members of the College.	
B. In your opinion is it desirable that women, after admission to the Membership, should be admitted by examination as Fellows of the College.	

(Please answer YES or NO.)

Dr. J. Ward Cousins was reappointed the representative of the College on the Central Midwives Board.

ANNUAL REPORT FOR 1906 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.[1]

III.

IF justification were required of the policy of the London County Council in combining under one authority the administrative functions of public health and elementary education, it is difficult to conceive how this could have been more completely accomplished than by the publication of the comprehensive and instructive report that lies before us.

The second appendix to this report is from the pen of Dr. James Kerr, the Council's medical officer for education. This report shows that, as regards the metropolis, a good beginning has been made to give effect to some of the chief recommendations of the Duke of Devonshire's Committee on Physical Deterioration. It will be remembered that one of the most important of these recommendations was that a medical examination should be made as to the mental and physical condition of every child on admission to an elementary school. Even a cursory reading of this report will suffice to indicate that a very serious amount of mental as well as of physical defect has been discovered among children in attendance at those of the London schools which have already been medically examined. To some of these we propose very briefly to allude.

It will surprise no one to hear that supreme importance is attached by the education authority to the medical inspection of the very youngest children—the "infants," as they are technically classed. It is at the earliest ages that slight defects or diseases have a profoundly modifying influence on the future; and it is of special importance that children of from three to five years should be examined in order that the beginnings of tuberculous bone and joint diseases amongst others may be detected, and thus permanent crippling may in all probability be avoided. With the staff at present at the department's disposal detailed examination is impracticable, but an attempt has been made by sampling to ascertain what medical inspection of infants really means and what it is likely eventually to lead to when effectually carried out. For this purpose examination was made by Dr. E. M. Niall of 14 schools, varying from the slum areas of Vauxhall, through the artizan areas of Lambeth, to the better class districts of Brixton and Norwood. The effect of environment appears at once from the fact that the survivors of the slum children at the age of five are as a rule sturdier and quicker than the more carefully nurtured children who have not been exposed to hard climatic conditions, but who on the other hand appear to present larger numbers of dull and backward children with anæmia, nasal obstruction, and glandular troubles. Two neighbouring schools, Lollard-street and Walnut Tree Walk, presented respectively the highest and the lowest number of defectives. Lollard-street, the school with the highest proportion (27 per cent.), is in a poor district abounding in fried-fish shops. Many of the mothers are wage-earners, returning home late at night too tired to look after the children. As might have been anticipated, semi-starvation and home neglect are factors in these unhealthy surroundings. The high percentage of defectives in this school was due in part to the presence of large numbers of children below the average in mental ability in one of the classes—a dullards' class containing 47 per cent. of children with some obvious defect. It is for such a class as this more particularly that early medical inspection is imperatively necessary, for by this means many cases of corneal ulceration, marginal blepharitis, incipient ophthalmia, and otitis may be detected and presumably remedied. Very harmful are what are designated "dirt conditions," especially in relation to the eyes, nose, and ears, ulceration of the corneal surface often leaving permanent damage. In many cases the parents will do nothing, even when asked by the teachers. These "dirt" inflammations in children of debilitated constitution are the chief conditions of slum schools.

But Dr. Kerr is careful to remind us that general medical inspection must eventually lead to the establishment of "school clinics" for treatment in ways which he takes pains to define. Without such treatment mere medical inspection is, in his judgment, incomplete and generally means time and trouble wasted. Most of these cases are neglected. Some few are attended to at hospital, but generally this is unsatisfactory and of late very many cases have been refused treatment.

If individual medical inspection of school children becomes general, we are warned that all the hospitals in London would not provide for the treatment of one-tenth of the children that would require treatment for diseases of the eyes, ears, and teeth alone. In order to cope with these cases Dr. Kerr suggests that the question of school clinics ought to become a subject of careful inquiry and as a question of elementary education should receive the early consideration of the County Council. To anyone fairly conversant with the untoward conditions normally obtaining among the infant denizens of our slum neighbourhoods it will occasion no surprise that of all the morbid conditions revealed by medical examination of school children by far the most important are those in which tuberculosis in one or other of its forms plays a prominent part. In the course of an investigation concerning the prevalence of tuberculosis in elementary schools Dr. Annie C. Gowdey reported on the condition of the spinal column of more than 400 young girls at Addison-gardens school. Of these girls, whose ages varied from six to 16 years, not less than 64 per cent. showed more or less abnormality. Very many of these girls had "round backs," whilst the scapulæ of not fewer than half of them were reported to be "growing out," with or without some lateral curvature. Unless the state of matters at this school be exceptionally bad, and if the condition of the children there is typical of what obtains among school children of the same age elsewhere, it is obvious that further investigation is required with a view of obviating some of the incidents of school life which, at this school at any rate, appear to have produced deplorable results. Dr. Kerr comments on the excessive prevalence of deformity of the back among girls as compared with boys, and points out that this is due to some specific cause, such, e.g., as a want of regular development of the trunk muscles induced by various constrictions and supports in the way of binders and corsets. Meantime, he suggests the desirability of directing the attention of teachers who superintend drill to the many causes that have been assigned for this condition, such as the imperfect lighting of schoolrooms, the habit of sitting cross-legged, and of standing with the weight of the body constantly resting on one leg.

The examination of girls in the secondary schools has also been carried out on a limited scale during 1906. In so doing Dr. Janet M. Campbell found it possible to conduct inquiry respecting the general physique of the girls with more detail than was possible in the case of the elementary school children before referred to. Out of 604 girls examined, 138 showed definite lateral curvature. Definite osseous deformity, not admitting of correction, was presented by seven of these girls, their ages being from 15 to 22 years. In all the other cases the deformity could be made to disappear by changes of posture. These girls migrate, for the most part, from the elementary schools, and their average standard of physique is not high. As they have all been previously examined medically, many defects had already been remedied. Of the 138 girls with spinal curvature, 10 were above and 37 were below the average in general physique.

Exaggerated and even alarmist reports having appeared from time to time to the effect that pulmonary tuberculosis is excessively prevalent among children of school age, the medical officer has very usefully addressed himself to the task of ascertaining how far children at school age are really affected with pulmonary tuberculosis, and also how far they are likely to be a danger to others. It should be premised that in the metropolitan schools there has long existed the salutary regulation that whenever a child is supposed to be suffering from consumption, and especially if he coughs and expectorates, he is forthwith excluded from school. Teachers similarly affected are likewise excluded for at least 12 months. The risks of infection from persons obviously suffering from pulmonary tuberculosis are therefore believed to be small. In order to ascertain by careful medical inspection the extent to which children of school age are actually suffering from pulmonary tuberculosis, the boys and girls, 1670 in number, in attendance at two large schools situate in Latimer-road and Addison-gardens respectively, were examined and the results tabulated for the present report.

---

[1] Previous notices of this report appeared in THE LANCET of Jan. 25th, p. 250, and Feb. 8th, 1908, p. 445.

congenital syphilis, small-pox, enteric fever, meningitis, fits, mumps, &c. The effects of these, if still traceable, should be recorded.

3. State if any case of, or death from, phthisis, &c., in family.

4. Note backwardness.

5. Age to be stated in years and months, thus $5\frac{4}{12}$.

6. Insufficiency, need of repair, and uncleanliness should be recorded (good, average, bad).

7. Without boots, standing erect with feet together, and the weight thrown on heels and not on toes or outside of feet.

8. Without boots, otherwise ordinary indoor clothes.

Height and weight may be recorded in English measures if preferred. n annual report, however, the final averages should be recorded in both English and metric measures.

9. General nutrition as distinct from muscular development or physique as such. State whether good, normal, below normal, or bad. Under-nourishment is the point to determine. Appearance of skin and hair, expression, and redness or pallor of mucous membrane are among the indications.

10. Cleanliness may be stated generally as clean, somewhat dirty, dirty. It must be judged for head and body separately. The skin of the body should be examined for cleanliness, vermin, &c.; and the hair for scurf, nits, vermin, or sores. At the same time ringworm and other skin diseases should be looked for.

11. General condition and cleanliness of temporary and permanent teeth, and amount of decay. Exceptional features, such as Hutchinsonian teeth, should be noted. Oral sepsis.

12. The presence or absence of obstruction in the naso-pharynx is the chief point to note. Observation should include mouth-breathing; inflammation, enlargement, or suppuration of tonsils; probable or obvious presence of adenoids, polypi; specific or other nasal discharge, catarrh, malformation (palate), &c.

13. Including blepharitis, conjunctivitis, diseases of cornea and lens, muscular defects (squints, nystagmus, twitchings), &c.

14. To be tested by Snellen's test types at 20 feet distance (= 6 metres). Result to be recorded in the usual way—e.g., normal V. = $\frac{6}{6}$. Examination of each eye (R. and L.) should, as a rule, be undertaken separately. If the V. be worse than $\frac{6}{6}$, or if there be signs of eye strain or headache, fuller examination should be made subsequently. *Omit vision testing of children under six years of age.*

15. Including suppuration, obstruction, &c.

16. If hearing be abnormal or such as interferes with class work, subsequent examination of each ear should be undertaken separately. *Apply tests only in general way in case of children under six years of age.*

17. Including defects of articulation, lisping, stammering, &c.

18. Including attention, response, signs of overstrain, &c. The general intelligence may be recorded under the following heads: (*a*) bright, fair, dull, backward; (*b*) mentally defective; (*c*) imbecile. *Omit testing mental capacity of children under six years of age.*

19. Under the following headings should be inserted particulars of diseased conditions actually present or signs of incipient disease. The extent of this part of the inspection will largely depend upon the findings under previous headings.

20. Include heart sounds, position of apex beat, anæmia, &c., in case of anything abnormal or requiring modification of school conditions or exercises.

21. Including physical and clinical signs and symptoms.

22. Including chorea, epilepsy, paralyses, and nervous strains and disorders.

23. Glandular, osseous, pulmonary, or other forms.

24. State particular form, especially in younger children.

25. Including defects and deformities of head, trunk, limbs. Spinal curvature, bone disease, deformed chest, shortened limbs, &c.

26. Including any present infectious, parasitical, or contagious disease, or any sequelæ existing. At each inspection the occurrence of any such diseases since last inspection should be noted.

27. Any weakness, defect, or disease not included above (e.g., ruptures) specially unfitting child for ordinary school life or physical drill, or requiring either exemption from special branches of instruction, or particular supervision.

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at Caxton House, Westminster, on Feb 13th, Dr. F. H. CHAMPNEYS being in the chair.

Medical Men v. *Midwives.*

The Standing Committee reported that a letter from the clerk of the Council transmitting a copy of a letter from the Local Government Board inclosing a letter from the executive committee of the Rural Midwives Association in regard to the question of the training of midwives, and the possibility of the grant of State aid in respect thereof, had been further considered. A letter from the clerk of the Council transmitting a copy of a memorandum addressed to the Secretary of State for the Home Department by Canon Dobell on the subject of the supply of midwives in rural districts was further considered at the same time. The committee reported that it had considered and settled a reply drafted by the chairman, and recommended that the same be sent to the Privy Council. The Board considered the letter which was discussed without being read *in extenso.* Dr. Champneys, in the course of his remarks, observed that there had been tension between medical practitioners and midwives in many parts of the country for some years. That condition of things must be recognised and a remedy must be found. If practitioners liked to coöperate with midwives more than they did there would be a *modus vivendi* found. Dr. Champneys also said he was not proud of the attitude of a large number of the members of the medical profession in the matter and quoted from a nursing journal some remarks alleged to have been made by a medical practitioner whose name Miss R. Paget said she could produce. Mr. E. Parker Young stoutly maintained that it should be widely known that the Midwives Act was unworkable. The medical profession had on all sides and by all manner of means shown that the Act was unworkable. The remedy was to pay medical men an adequate sum when they were called in on the advice of midwives. The Government must be put in full possession of all the facts of the case. If the Government was going to do any good it must take action in the matter. The Government was greatly to blame for not grappling with the difficulty.

The Board decided to send the letter to the Privy Council and the following is a copy kindly supplied for publication by the Board:—

CENTRAL MIDWIVES BOARD.

Caxton House, Westminster, London, S.W.,
Feb. 15th, 1908.

SIR,—I am directed to advert to your letter of the 12th December, 1907, transmitting a copy of a letter from the Local Government Board inclosing a letter from the executive committee of the Rural Midwives Association in regard to the question of the training of midwives and the possibility of the grant of State aid towards the cost of such training. These matters have now received the careful consideration of the Board and I am to forward to you for the information of the Lord President the observations of the Board on the questions raised in your letter.

With regard to "the number of midwives likely to be available on April 1st, 1910, their distribution in urban and rural districts, to what extent the supply will probably fall short of the requirements, and how the deficiency is to be made good," the Central Midwives Board has not hitherto considered that these questions fall within the scope of the Act, "to secure the better training of midwives and to regulate their practice," although many of its members who are interested in the larger question of the care of the poor mothers of England and their infants have taken part in movements with that object. The Board is, however, glad to do what it can towards the solution of the difficulties, and is earnestly considering the subject with a view to making recommendations at an early date. The returns of the local supervising authorities under Section 8 (5) of the Midwives Act, 1902, are the only data from which the Board can ascertain the approximate number of practising midwives and their distribution in the urban and rural districts. These returns are now coming in, and it is hoped that by March the Board will be in possession of tolerably complete information as to the number of midwives practising in England and Wales at the present time. But in taking these figures as the basis of an estimate of the number likely to be available on April 1st, 1910, it must be remembered that undoubtedly a large number of uncertified women still practise as midwives. There are no means available of ascertaining to what extent the total number of practising midwives will be affected by the fact that these uncertified women will be debarred from legitimate practice after March 31st, 1910.

As regards the opinion of Mrs. Hobhouse quoted in your letter, but not otherwise within the knowledge of the Board, it may be well to inform the Lord President that that lady no doubt refers to the action of the Board in removing the Cottage Nurses' Home, Kingswood, Bristol, from the list of recognised training schools. This institution has neither a visiting nor a resident medical staff and its work is purely extern. It is situated about three miles from Bristol, in which city the Board recognises two training schools, the Royal Infirmary and the General Hospital. Mrs. Hobhouse was interested in the Kingswood Nurses' Home and warmly supported its application for approval as a training school. After considerable discussion the Board granted its approval in March, 1905. Dr. James McMurray was appointed lecturer to the pupil midwives and training was carried on under these conditions until June, 1906. Dr. McMurray then resigned his post and the pupil midwives received their theoretical training from Dr. W. C. Swayne, professor of midwifery at University College, Bristol. This course met with the approval of the Board, but as Dr. Swayne was a recognised teacher there was no longer any necessity for the recognition of the Kingswood Nurses' Home in order to enable training to be carried on there. The Board accordingly, on the revision of the list of training schools in April, 1907, removed the name of Kingswood Nurses' Home. This in no way interferes with the training at the home, which continues under precisely the same conditions as before the name was removed from the list. 21 candidates were sent up from the home while it was a recognised training school. Of these, 13 passed and 8 failed. Since the change was made the number of candidates has been 13, with 11 successes and 2 failures, the percentage of failure falling from 38 to 15.

The opinion as quoted alleges that the Board (*a*) has "raised the standard of examination," (*b*) has "lengthened the syllabus," (*c*) has "refused to recognise several old-established training schools." As regards the first, (*a*), the standard aimed at by the Board has always been strictly limited to such knowledge as it would be dangerous for a midwife to lack. It must be remembered that imperfect instruction is one of the objections alleged against midwives, especially by members of the medical profession. The Board has always endeavoured to restrict the scope of its examinations to this standard, and these are visited by many members of the Board, including the chairman, who makes a rule of being present if possible at every examination. To require less than is now required would not, in the opinion of the Board, be safe. As regard the second, (*b*), "lengthening the syllabus," the Board does not quite understand the meaning of the phrase, as there has been no "syllabus" in existence to lengthen. But possibly it may mean much the same as (*a*), and, in such case, the answer of the Board would be congenial career for educated natives of the country, and by fully utilising this source of supply the Government will avoid the expense of materially enlarging the Indian Medical Service or of importing specially trained officers from England for the present. At least it will be necessary to insist upon a training in Europe as a qualification for employment, as the experience gained thereby would be wider and more valuable than could as yet be obtained in India. A health officer who has undergone such a training and is at the same time possessed of an intimate acquaintance with the customs and prejudices of the people would be singularly well equipped for the difficult and delicate duties connected with sanitation in India. He would on the one hand have the best scientific knowledge available, and he would on the other be able to avoid arousing that opposition which the application of Western sanitary science to Eastern conditions too often excites. The Governor-General in Council does not suggest that the combination of these qualities is not found in European officers or that it will always be found in natives of India. He knows that the contrary is the case. He proposes, therefore, that the new appointments shall be open to both classes alike, but on grounds of economy preference would naturally be given to Indian candidates when men with the necessary qualifications are forthcoming.

7. For towns with a population between 20,000 and 100,000 a medical officer of health will also ordinarily be necessary, but financial considerations will render it compulsory to accept a somewhat lower standard of scientific attainments than that prescribed for the larger cities. These appointments may, the Government of India think, be recruited from natives of India of the civil assistant surgeon class, who on the completion of their medical training have taken a special course in public health at one of the medical colleges. The appointment of such an officer may not be necessary for every town of the class referred to, and where the head-quarters town of a district is small it will probably be possible to combine the appointment of health officer with the medical charge of the district. In that case it will probably be desirable that the civil surgeon should be chairman of the sanitary subcommittee where there is one.

8. The Government of India are advised that it should be laid down as an inviolable rule that a medical officer of health should not be allowed to undertake private practice. Although a small amount of such medical work might not interfere with the performance of the health officer's proper duties, yet if private practice is once allowed it is impossible to put a limit to it and it is, therefore, best to forbid it altogether. This restriction will necessitate the salaries of health officers being fixed on a more liberal scale than would otherwise be required, but the advantage of securing the officers' whole time and undivided energies far outweighs the somewhat problematical economy that might be effected by permitting private practice.

Sanitary Inspectors.

9. The subordinate supervising staff of the Conservancy Establishment also calls urgently for improvement. In most towns there is an official whose functions resemble those performed by an inspector of nuisances in England. Except in the presidency towns, however, and in the Madras municipalities, it is very rare to find in this position a man who has any technical knowledge of his subject. The Government of India are assured that one of the most crying needs of municipal sanitation in India is a body of men fit to undertake the duties of sanitary supervision, which are performed by inspectors of nuisances in Great Britain. It is urged that medical officers of health will not and cannot be expected to undertake work of this subordinate character and that the existing establishments of untrained supervisors and overseers are not able to give the health officer the assistance which he has a right to demand. If this assistance is denied, many petty and irksome duties will be imposed on the health officer, and suitable men will not be obtained for that office. Just as a trained subordinate acts as a link between the executive engineer and the working labourer, so a trained subordinate is required by the executive sanitary officer. It is imperative, therefore, that measures should be taken without delay to remedy this defect in the administration. The strength of the establishment required will depend not on the population alone but on other local circumstances also. In the large cities a trained inspector will probably be needed for each sanitary division, with perhaps a chief inspector in addition. For other towns the number of inspectors required will vary with the population, the area, and sanitary condition. In many a single officer will ordinarily prove sufficient.

10. The training of these sanitary inspectors is a question which will require very careful consideration. The standard required should be that prescribed by the Royal Sanitary Institute, with whom arrangements could no doubt be made for the issue of certificates to successful candidates. If that is thought desirable the course of instruction should embrace lectures in elementary physics, physiology, general hygiene, and minor sanitary engineering. Admission to the courses of instruction should be confined to candidates who have passed some examination not lower than the school final or the university matriculation examination and are of good physique, satisfactory character, and suitable caste and social status, the consideration to be borne in mind in fixing this last qualification being that a sanitary inspector must be able to move freely among all classes of the population. To attract men of the right stamp it will be necessary to offer good pay. A scale of salaries rising from Rs. 50 to Rs. 150 will probably prove suitable in most provinces.

Advantages of Certainty of Tenure.

11. There remains the important question whether the medical officers of health and sanitary inspectors should be formed into a regular provincial sanitary service, or whether each local authority should be allowed to recruit its own staff independently. The objections urged against the latter course are: (1) that a career which is limited to employment by local authorities on uncertain terms and without prospect of pension will not attract candidates of the right stamp if, indeed, it attracts candidates at all; and (2) that the insecurity of tenure of appointments under local authorities will tend to deter young men from qualifying themselves for such appointments. The duties of a sanitary officer will of necessity often bring him into conflict with members of the local authority or their relatives, and if he is merely the servant of the board or council he will either neglect his duty in such cases or perform it at the risk of losing his post. On the other hand, it is argued that the creation of a provincial service of sanitary officers will conflict with one of the main principles of local self-government and it is urged that in no branch of local administration is local control so necessary as in matters connected with sanitation. The Government of India could not agree to any proposal which did not leave to the local authority the control of its executive officers, whether of the sanitary or any other establishment. On the other hand, they are convinced that in the case of the sanitary officers certainty of tenure during good conduct must be assured. How this can best be secured is a question upon which the Governor-General in Council would like to have the opinions of local governments. It is not necessary to insist upon uniformity of treatment and arrangements which are expedient in one province may not be so suitable in another. The creation of a provincial service offers one solution, and for the purpose of attracting candidates this is probably the best solution. When a member of such a service held a post under a local authority he would be in a position corresponding to that of a member of the subordinate medical service in the employ of the municipal or district board. An alternative to the creation of a provincial service is for the Government to prescribe: (1) the minimum number of sanitary appointments for each local authority; (2) the minimum salary to be given to the incumbent of such appointments; and (3) the professional qualifications to be required of incumbents. This would possibly afford a prospect of employment sufficiently good to induce candidates to undergo the qualifying course of instruction. To secure fixity of tenure it would be necessary to provide that no medical officer of health or sanitary inspector should be removeable from office without the sanction of the local Government in the case of the former or of the Sanitary Commissioner or perhaps the Sanitary Board in the case of the latter. Regulations somewhat similar to these exist in England and Scotland and are necessary to secure the employment of properly qualified men and to guarantee protection against arbitrary treatment in retaliation for the fearless and efficient performance of duty.

12. The Government of India do not propose to discuss at present the thorny question of sanitation in rural areas. Assistant health officers are probably necessary in some districts and trained inspectors would often, no doubt, be useful to local boards to undertake special inspections or to provide sanitary measures on special occasions, such as fairs

scattering of the drop of moisture which, I understand, the closing of the lid brings on to the eye. For the figures themselves, most of which are wholly new to me, I can offer no more explanation than for those which come in dreams.

Having lost one sense and suffered diminution of others a man may feel some misgivings as to intellectual power and consequently I consulted an expert who is among my bedside visitors on this matter. To him I recited Prop. 5 of the First Book of Euclid, the wooden horse episode from Virgil commencing "Timeo Danaos," and also excerpts from poets, politicians bygone and present, and also answered his questions. In the end he seemed to consider that the mind was quite clear and the memory unusually so.

Both the doctors attending me agree that the spinal cord is affected and that this is due to over-exertion. Both of them have large experiences and practices, and have further told me that the reason of my lasting out so well is largely due to the cheerful view I have taken of what is considered a singularly distressing situation. This testimony as to the value of cheerfulness makes me desirous to use the gift, if possible, in aid of fellow-sufferers and to suggest that the patient, no matter how great the pain he suffers, has a duty to the medical man and to the nurse who may be attending him. Both of these have their own share of human ills to suffer and it does not require great intelligence to understand that a harassed and often overworked medical man finds it a great effort to conjure up the pleasant and hopeful smile with which he usually meets his patients. The sight of a man or woman making a good effort to be patient under extreme pain and to show some slight consideration for those around them has a beneficial effect on all who witness it and was the last lesson taught from Calvary. Perplexed and grievously assailed by misgivings as a man must be who struggles for a living in the dark, the writer has never doubted the advice given him by one who has been honourably mentioned in THE LANCET—to try to get some good out of the malady for himself and others. Neither has he doubted that the Hand which struck the blow gave also the ability to take it cheerfully.

As a press reporter and in another capacity I have frequently heard the medical opinion that a strong faith, however rugged, in the unfailing goodness of the Creator greatly helps the sick to bear pain patiently and even to meet death smilingly. Such a belief, then, must necessarily greatly help the medical man in his beneficent work and for this reason alone, if for no other, is worth fostering. It is a belief coming through home and school education, both of which institutions are necessary to the proper teaching of religion. From a forecast of the Education Bill shortly to be introduced it is clear that if it becomes law most of our children will stand a great risk of being deprived of this curative and comforting belief. It seems fit, therefore, that one who greatly honours the medical profession and has so often witnessed the good done by its members should entertain a strong hope that they will find the time to object to any attempt being made to make the bed of the sick and dying less comfortable.

MEDICINE AND THE LAW.

Voice-Production.

AFTER a prolonged hearing an action has been concluded in which a plaintiff named Horspool sued Dr. W. H. Cummings, president of the Incorporated Society of Musicians and principal of the Guildhall School of Music, for slander. Mr. Horspool claims, or claimed, to have devised a system of voice-production for singers and is the managing director with a salary of £1000 a year of a company (joined with him as plaintiffs in the action) formed for the carrying out of his system, the advertisements of which company had formed the subject of forcible observations by Dr. Cummings at a meeting of the Incorporated Society of Musicians at Buxton in January, 1907. The gist of Dr. Cummings's observations may be gathered from that portion of the plaintiff's statement of claim, which said that the words spoken meant "that Mr. Horspool was an impudent quack and that he had duped and imposed upon the public and that he carried on a fraudulent and dishonest business." The defence resolved itself into the question whether the words used were "fair comment upon a matter of public importance." The judge ruled that the matter was one of public importance and the jury, satisfied that the comment was fair, found a verdict for the defendant who is to be congratulated upon the result thus achieved. The methods adopted by the plaintiff with a view to produce perfection in the singing voices of those desirous of attaining such perfection need not be recapitulated, but it is interesting to note the use made by him of the fact that he had submitted 20 of his pupils to examination by Mr. Milsom Rees before and after they had been under his tuition. He claimed that Mr. Rees had been struck with astonishment at his discovery, saying, "It is wonderful. What you have shown me would surprise a layman, but it is even more extraordinary to a doctor." In spite of this alleged admiration on the part of a medical witness whose evidence, if favourable, would have been of considerable value to him, the plaintiff did not call Mr. Rees as a witness, but the defendant's legal advisers, with what Mr. Justice Darling described as "an amount of courage which some advocates would consider recklessness," had served him with a subpœna, and calling him into the witness-box proceeded to examine him without having any "proof" of what answers he would give to their questions. The bold course thus taken was justified, for in the circumstances the plaintiff and his counsel could not do otherwise than absolve the witness from any obligation of professional reticence without laying themselves open to inferences which would have been almost as damaging as the evidence actually given. Mr. Rees had no recollection of having ever expressed wonder or admiration, and his evidence must have contributed not inconsiderably to the defendant's ultimate success. As a matter of fact, the result of his second examination had been to show that in three cases out of the 20 there had been rupture of the ligaments of the vocal cords due apparently to excessive tension produced by the plaintiff's methods, and he was able to point out various absurdities in the measures alleged to have been adopted for cultivating the voice, some of them based upon ideas as to the anatomy of the organs involved which he characterised tersely as bosh. Expert evidence was also given on behalf of the defendant by Mr. H. H. Hulbert, lecturer on voice-production to the London County Council and at the University of London. His testimony, and also that of Mr. Rees so far as it consisted of expert evidence, was directed towards pointing out the absurdity of the plaintiff's promise to produce results in themselves impossible and to explaining that it was equally impossible that the treatment which he professed to apply should have any effect approximating to that which he claimed for it. A feature in the case frequently to be observed in trials of a similar character consisted in the calling of witnesses who, no doubt in good faith, testified to benefits which, they alleged, had been derived by them from the treatment advertised. It is, however, natural that those who fancy that they have been benefited should proffer their evidence rather than that those who believe themselves to have been deceived by false hopes should come forward and admit their aspirations and their disappointment.

ASYLUM REPORTS.

Roxburgh, Berwick, and Selkirk District Asylum (Annual Report from May, 1906, to May, 1907).—On May 15th, 1906, there were on the register of this asylum 331 patients (149 males and 182 females), including both private and parish cases. During the year 74 patients (47 males and 27 females) were admitted, and of these 11 were private patients. Dr. J. Carlyle Johnstone, the medical superintendent, reports that on the completion of the extensions and alterations which are at present being carried out in the asylum there will be ample accommodation for all cases of insanity occurring in the district for the care and treatment of which a reasonable sum can be paid and for a considerable number of persons of moderate means from other counties. £40 a year is the rate charged for private patients from the district and £45 for cases from other parts of the country; but patients in straitened circumstances who are settled in the district are received at lower rates when satisfactory proof is furnished that the full rate cannot be paid. Hereditary predisposition to mental disorder was found to exist in 43 of the cases admitted. The physical condition of the patients was good or average in 11 per cent., bad in 82 per cent., and very bad in 7 per cent., more than

A letter was read from the President of the General Medical Council stating that a committee of the Council had been appointed to prepare a fresh edition of the British Pharmacopœia, and inviting the College to send to the committee before April 30th next any recommendations or suggestions. A committee was appointed to consider the matter.

A letter was read from the President and secretaries of the Geological Society of London thanking the Council for the address presented to the society at the celebration of the centenary in September last.

The PRESIDENT reported that he had chosen Mr. W. Watson Cheyne as Bradshaw lecturer for the ensuing collegiate year.

The PRESIDENT reported that the vacancy on the Board of Examiners in Dental Surgery, occasioned by the expiration of the period of office of Mr. W. A. Maggs, would be filled up after the ordinary Council meeting in March. Mr. Maggs is eligible for re-election.

Upon the suggestion of the PRESIDENT, a small committee was appointed to keep the Council informed as to what is being done from time to time regarding the medical inspection of school children and the arrangements for teaching elementary hygiene in training colleges and schools.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE following circular containing a schedule of medical inspection has been issued by the Board of Education to local education authorities. The schedule has been drawn up in response to requests which the Board of Education has received for further and more definite guidance as regards the details of the work of medical inspection. Sir Robert Morant writes as follows to the local education authorities:—

> The Board have been pressed by many local education authorities to issue a complete set of forms for use in carrying out the work directly or incidentally involved in the performance of these new duties. Any forms which experience of the working of the Act may show to be necessary or desirable will be issued in due course, but for the present the Board think it expedient to leave considerable latitude, subject to the considerations hereinafter set out, in regard to the particular forms or schedules to be used in different cases or circumstances. The chief difficulties to be considered are administrative rather than educational or scientific. There is comparatively little dispute as to the end in view or as to the means which, from the technical standpoint of medical science and practice, should be adopted for its complete attainment. But the existing resources of local education authorities are (for practical purposes, at all events) not unlimited, the feelings and prejudices of parents have to be considered, and a new element has to be introduced into school life and organisation with the least possible disturbance and inconvenience. Moreover, in this case two departments of local public administration are brought for the first time into organic connexion—those of public health and of public education.
>
> The Board are fully aware of these difficulties, and in preparing their Memorandum and Regulations it was necessary for them to consider what system would best reconcile the theoretical and practical considerations, and overcome the divergence between the ultimate end and the end immediately attainable, or between the methods which are scientifically desirable and those which can be applied in existing circumstances at the initiation of the work under the Act.
>
> In the accompanying schedule the Board indicate the particulars, attention to which they regard as constituting the minimum of efficient medical inspection, and they consider that at least these particulars should be included in any other schedule which the local education authority may authorise for use in their schools. It deliberately excludes many points of anthropometric or statistical interest which are worthy of attention, and which it is hoped may receive attention in suitable districts. Nor does it profess to lay down the lines of a clinical study or of a scientifically complete medical examination. It is intended to indicate the methods which, in the Board's opinion, should be followed and the particulars which should be attended to for the purpose of determining the fitness of the individual child for school life, to guide the authority in adapting education to the peculiarities or abnormalities of the child and to prepare the way for measures for the amelioration of defects in the child or its environment. A more elaborate and complete form could readily be devised, but the Board's knowledge of the circumstances in which the work is to be done leads them to believe that greater elaboration would in the majority of cases defeat its own end.
>
> If this schedule is properly used, few cases of serious physical weakness or defect will escape detection. Where the ordinary inspection shows the need of further and more searching medical examination a supplementary blank form should be used in which particular defects or diseases should be fully recorded. It may facilitate inspection if the schedule is printed on cards (8" by 5" or 10 by 6"). The notes are included in the attached form for the convenience of the school medical officer, and should not be reprinted on the cards. Of course it is not necessary that negative findings on all the points mentioned in the notes should be recorded. It will be noticed that a space is reserved in the schedule for "General Observations"; this may conveniently be used to record a general summary of the condition of the child, and any information which may be available as to the home environment, or other conditions affecting its health. It is considered that the inspection of each child should not occupy on the average more than a few minutes, and that the child need only, as a rule, have its clothes loosened or be partially undressed. Time may be saved in the actual inspection by the medical officer if the entries in some of the spaces are filled in by the school authorities before his visit. The four columns in the schedule are designed for the four inspections required during school life. With regard to items 17 to 24 of the schedule, while it is necessary that all indications of diseased or unsound conditions should be thoroughly investigated, needless medical examination of healthy children should, for obvious reasons, be avoided.
>
> Where children are found to belong to that class of "defectives" for whose education special provision is or ought to be made under the Statutes relating to such children, such cases should be made the subject of a special report to the local education authority.
>
> *All entries of the results of inspection in each individual case must be regarded as confidential.*

With this circular specimen cards were inclosed which we have already noticed in THE LANCET, but cards will not be supplied with the copies of the circular which are placed on sale.

The following is the schedule accompanying Sir Robert Morant's circular letter to local education authorities:—

SCHEDULE OF MEDICAL INSPECTION.

I.—Name .... Date of Birth[1] ....
Address .... School ....

II.—Personal History:[*]

(a) Previous Illnesses of Child (before admission).

Measles.	Whooping-cough.	Chicken-pox.	Scarlet fever.	Diphtheria.	Other illnesses.[2]

(b) Family Medical History (if exceptional).[3]

—	I.	II.	III.	IV.
1. Date of inspection				
2. Standard and regularity of attendance[4]				
3. Age of child[5]				
4. Clothing and footgear[6]

NOTES FOR INSPECTING OFFICER.

1. Date of birth to be stated exactly, date of month and year.

2. "Other illnesses" should include any other serious disorder which must be taken into account as affecting, directly or indirectly, the health of the child in after-life, e.g., rheumatism, tuberculosis,

from these diseases in the other towns ranged upwards, however, to 2·9 in Oldham, 3·1 in Hanley, 3·3 in Sunderland, and 4·7 in Merthyr Tydfil. The fatal cases of whooping-cough in the 76 towns, which had been 190 and 192 in the two preceding weeks, declined last week to 154; they caused annual death-rates, however, equal to 1·8 in Oldham, 1·9 in Aston Manor, 2·1 in Ipswich, 2·5 in Rotherham, and 3·0 in Sunderland. The 78 deaths from measles exceeded the number in the previous week by seven; the highest rates from this disease were 1·1 in Salford and in Swansea, 1·5 in Hanley, and 2·7 in Merthyr Tydfil. Of the 47 fatal cases of diphtheria, showing a considerable decrease from the numbers in recent weeks, 18 occurred in London and its suburban districts, five in Manchester and Salford, and three in Cardiff. The 40 deaths from scarlet fever included 16 in London, two in West Ham, three in Liverpool, and four in Manchester and Salford. The 26 deaths referred to "fever" showed a slight increase; the four fatal cases in Norwich were equal to an annual rate of 1·7 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the ten preceding weeks from 5581 to 3867, had further fallen to 3806 on Feb. 15th; during the week ending on that day 473 new cases were, however, admitted to these hospitals, against 380, 405, and 433 in the three previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had declined in the four preceding weeks from 499 to 395, rose again to 451 in the week under notice, and exceeded by 79 the corrected average number in the corresponding week of the five years 1903-07. The causes of 59, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Manchester, Salford, and in 44 other smaller towns. Ten uncertified causes of death were, however, registered in Birmingham and in Liverpool, and three each in Sheffield, Gateshead, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 22·3 and 23·5 per 1000 in the two preceding weeks, declined to 21·4 in the week ending Feb. 15th, but exceeded by 2·8 the mean rate during the same week in the 76 English towns. Among the eight Scotch towns the death-rates ranged from 14·3 and 17·4 in Aberdeen and Greenock, to 22·9 in Glasgow and 29·6 in Perth. The 755 deaths in these eight towns showed a decline of 72 from the high number returned in the previous week, and included 114 which were referred to the principal epidemic diseases, against 142, 123, and 132 in the three preceding weeks; of these, 55 resulted from measles, 18 from whooping-cough, 18 from diarrhœa, eight from "fever," eight from diphtheria, seven from scarlet fever, but not one from small-pox. These 114 deaths were equal to an annual rate of 3·2 per 1000, which exceeded by no less than 2·0 the mean rate last week from the same diseases in the 76 English towns. The 55 fatal cases of measles showed a decline of nine from the number returned in each of the two previous weeks, and included 47 in Glasgow and three in Edinburgh and in Aberdeen. Of the 18 deaths from whooping-cough, fewer by 14 than those in the previous week, 11 were returned Glasgow and two both in Edinburgh and in Leith. The 18 deaths attributed to diarrhœa exceeded the numbers in recent weeks; 11 occurred in Glasgow, two in Dundee, and two in Leith. Of the eight deaths referred to "fever," seven were certified as cerebro-spinal meningitis and one as enteric fever; these eight deaths included five in Glasgow, two in Paisley, and one in Edinburgh. Five of the eight fatal cases of diphtheria were returned in Glasgow; and the seven deaths from scarlet fever included three in Glasgow and two in Paisley. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 179 and 171 in the two preceding weeks, rose again to 176 in the week under notice, and exceeded by seven the number from the same diseases in the corresponding week of last year. The causes of 28, or 3·7 per cent., of the deaths in these towns last week were not certified or not stated; in the 76 English towns the proportion of these uncertified deaths last week did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had declined in the four preceding weeks from 31·2 to 22·3 per 1000, rose again to 24·7 in the week ending Feb. 15th. During the first seven weeks of the current quarter the death-rate in the city averaged 26·4 per 1000, whereas the mean rate during the same period did not exceed 18·1 in London and 19·7 in Edinburgh. The 187 deaths of Dublin residents registered last week showed an increase of 18 upon the number in the previous week, and included three which were referred to the principal epidemic diseases, against nine, six, and four in the three preceding weeks; these three deaths included one each from measles, diphtheria, and whooping-cough, no death being registered either from scarlet fever, "fever," diarrhœa, or small-pox. These three deaths from epidemic diseases were equal to an annual death-rate of but 0·4 per 1000, the death-rate from the same diseases last week being 1·1 in London and 1·3 in Edinburgh. The 187 deaths from all causes in the city last week included 30 of infants under one year of age and 60 of persons aged upwards of 60 years; the deaths of infants showed an increase, while those of elderly persons were fewer than in any recent week. Four inquest cases and four deaths from violence were registered during the week, and 76, or 40·6 per cent., of the deaths occurred in public institutions. The causes of six, or 3·2 per cent., of the deaths in the city last week were not certified; in London the causes of all but two of the 1752 deaths last week were duly certified, while in Edinburgh the proportion of uncertified deaths was 3·6 per cent.

VITAL STATISTICS OF LONDON DURING JANUARY, 1908.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 8·4 per 1000 of the population, estimated at 4,795,757 persons in the middle of the year; in the three preceding months the rates were 13·6, 11·4, and 9·1 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, Chelsea, the City of Westminster, St. Marylebone, Hampstead, and the City of London; the highest rates were Hackney, Bethnal Green, Stepney, Poplar, Bermondsey, and Deptford. The prevalence of scarlet fever again showed a marked decline last month; among the various boroughs this disease was proportionally most prevalent in Hackney, Bethnal Green, Stepney, Poplar, Bermondsey, Camberwell, and Deptford. The Metropolitan Asylums hospitals contained 3866 scarlet fever patients at the end of last month, against 5395, 5600, and 4956 at the end of the three preceding months; the weekly admissions averaged 423, against 778, 621, and 458 in the three preceding months. The prevalence of diphtheria showed no variation from that recorded in the previous month; this disease was proportionally most prevalent in Stoke Newington, Hackney, Bethnal Green, Wandsworth, Greenwich, Lewisham, and Woolwich. The number of diphtheria patients remaining under treatment in the Metropolitan Asylums hospitals at the end of last month was 1135, against 1252, 1277, and 1168 at the end of the three preceding months; the weekly admissions averaged 150, against 199, 179, and 155 in the three preceding months. Enteric fever was considerably less prevalent than it had been in any of the four preceding months; the greatest proportional prevalence of this disease was recorded in Hammersmith, Chelsea, Holborn, Bethnal Green, Poplar, and Bermondsey. There were 96 enteric fever patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 123, 128, and 119 at the end of the three preceding months; the weekly admissions averaged 12, against 18 in each of the two preceding months. Erysipelas was proportionally most prevalent in Fulham, Hackney, Bethnal Green, Stepney, Poplar, and Bermondsey. The 19 cases of puerperal fever notified during the month included two in Bethnal Green and three each in Shoreditch, Stepney, and Wandsworth. Ten cases of cerebro-spinal meningitis were notified, of which two belonged to Hackney, two to Lambeth, and one each to St. Marylebone, Islington, Stoke Newington, Finsbury, Poplar, and Southwark.

The mortality statistics in the table relate to the deaths

A letter was read from the President of the General Medical Council stating that a committee of the Council had been appointed to prepare a fresh edition of the British Pharmacopœia, and inviting the College to send to the committee before April 30th next any recommendations or suggestions. A committee was appointed to consider the matter.

A letter was read from the President and secretaries of the Geological Society of London thanking the Council for the address presented to the society at the celebration of the centenary in September last.

The PRESIDENT reported that he had chosen Mr. W. Watson Cheyne as Bradshaw lecturer for the ensuing collegiate year.

The PRESIDENT reported that the vacancy on the Board of Examiners in Dental Surgery, occasioned by the expiration of the period of office of Mr. W. A. Maggs, would be filled up after the ordinary Council meeting in March. Mr. Maggs is eligible for re-election.

Upon the suggestion of the PRESIDENT, a small committee was appointed to keep the Council informed as to what is being done from time to time regarding the medical inspection of school children and the arrangements for teaching elementary hygiene in training colleges and schools.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE following circular containing a schedule of medical inspection has been issued by the Board of Education to local education authorities. The schedule has been drawn up in response to requests which the Board of Education has received for further and more definite guidance as regards the details of the work of medical inspection. Sir Robert Morant writes as follows to the local education authorities:—

> The Board have been pressed by many local education authorities to issue a complete set of forms for use in carrying out the work directly or incidentally involved in the performance of these new duties. Any forms which experience of the working of the Act may show to be necessary or desirable will be issued in due course, but for the present the Board think it expedient to leave considerable latitude, subject to the considerations hereinafter set out, in regard to the particular forms or schedules to be used in different cases or circumstances. The chief difficulties to be considered are administrative rather than educational or scientific. There is comparatively little dispute as to the end in view or as to the means which, from the technical standpoint of medical science and practice, should be adopted for its complete attainment. But the existing resources of local education authorities are (for practical purposes, at all events) not unlimited, the feelings and prejudices of parents have to be considered, and a new element has to be introduced into school life and organisation with the least possible disturbance and inconvenience. Moreover, in this case two departments of local public administration are brought for the first time into organic connexion—those of public health and of public education.
>
> The Board are fully aware of these difficulties, and in preparing their Memorandum and Regulations it was necessary for them to consider what system would best reconcile the theoretical and practical considerations, and overcome the divergence between the ultimate end and the end immediately attainable, or between the methods which are scientifically desirable and those which can be applied in existing circumstances at the initiation of the work under the Act.
>
> In the accompanying schedule the Board indicate the particulars, attention to which they regard as constituting the minimum of efficient medical inspection, and they consider that at least these particulars should be included in any other schedule which the local education authority may authorise for use in their schools. It deliberately excludes many points of anthropometric or statistical interest which are worthy of attention, and which it is hoped may receive attention in suitable districts. Nor does it profess to lay down the lines of a clinical study or of a scientifically complete medical examination. It is intended to indicate the *methods* which, in the Board's opinion, should be followed and the particulars which should be attended to for the purpose of determining the fitness of the individual child for school life, to guide the authority in adapting education to the peculiarities or abnormalities of the child and to prepare the way for measures for the amelioration of defects in the child or its environment. A more elaborate and complete form could readily be devised, but the Board's knowledge of the circumstances in which the work is to be done leads them to believe that greater elaboration would in the majority of cases defeat its own end.
>
> If this schedule is properly used, few cases of serious physical weakness or defect will escape detection. Where the ordinary inspection shows the need of further and more searching medical examination a supplementary blank form should be used in which particular defects *or diseases should be fully recorded*. It may facilitate inspection if the schedule is printed on cards (8" by 5" or 10" by 6"). The notes are included in the attached form for the convenience of the school medical officer, and should not be reprinted on the cards. *Of course it is not* necessary that negative findings on all the points mentioned in the notes should be recorded. It will be noticed that a space is reserved in the schedule for "General Observations"; this may conveniently be used to record a general summary of the condition of the child, and any information which may be available as to the home environment, or other conditions affecting its health. It is considered that the inspection of each child should not occupy on the average more than a few minutes, and that the child need only, as a rule, have its clothes loosened or be partially undressed. Time may be saved in the actual inspection by the medical officer if the entries in some of the spaces are filled in by the school authorities before his visit. The four columns in the schedule are designed for the four inspections required during school life. With regard to items 17 to 24 of the schedule, while it is necessary that all indications of diseased or unsound conditions should be thoroughly investigated, needless medical examination of healthy children should, for obvious reasons, be avoided.
>
> Where children are found to belong to that class of "defectives" for whose education special provision is or ought to be made under the Statutes relating to such children, such cases should be made the subject of a special report to the local education authority.
>
> *All entries of the results of inspection in each individual case must be regarded as confidential.*

With this circular specimen cards were inclosed which we have already noticed in THE LANCET, but cards will not be supplied with the copies of the circular which are placed on sale.

The following is the schedule accompanying Sir Robert Morant's circular letter to local education authorities:—

NOTES FOR INSPECTING OFFICER.

1. Date of birth to be stated exactly, date of month and year.

2. "Other illnesses" should include any other serious disorder which must be taken into account as affecting, directly or indirectly, the health of the child in after-life, e.g., rheumatism, tuberculosis,

of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased had previously resided. During the five weeks ending Feb. 1st the deaths of 8030 persons belonging to London were registered, equal to an annual rate of 17·5 per 1000; in the three preceding months the rates were 13·5, 14·5, and 15·2 per 1000 respectively. The lowest death-rates last month were 11·1 in Hampstead, 13·9 in Lewisham, 14·1 in Woolwich, 14·2 in Fulham, 14·5 in Greenwich, and 14·7 in the City of Westminster; the highest rates were 20·8 in Poplar, 21·4 in Bethnal Green, 21·7 in the City of London, 21·9 in Bermondsey, 22·4 in Shoreditch, 24·1 in Holborn, and 24·3 in Finsbury. The 8030 deaths from all causes included 567 which were referred to the principal infectious diseases; of these, 129 resulted from measles, 83 from scarlet fever, 118 from diphtheria, 140 from whooping-cough, 16 from enteric fever, one from ill-defined pyrexia, and 80 from diarrhœa. The lowest death-rates last month from these diseases were recorded in Hammersmith, the City of Westminster, Hampstead, St. Marylebone, Stoke Newington, and Lambeth; and the highest rates in Hackney, Holborn, Finsbury, Bethnal Green, Stepney, Poplar, Bermondsey, and Lewisham. The 129 deaths from measles were 54 below the corrected average number in the corresponding periods of the five preceding years; this disease was proportionally most fatal last month in Paddington, Kensington, Fulham, St. Pancras, Stepney, and Poplar. The 83 fatal cases of scarlet fever were 34 in excess of the corrected average number; among the various boroughs this disease showed the greatest proportional mortality in Hackney, Shoreditch, Bethnal Green, Poplar, and Bermondsey. The 118 deaths from diphtheria were 41 above the corrected average number in the first five weeks of the years 1903-07; this disease was proportionally most fatal in Hackney, Holborn, Finsbury, the City of London, and Lewisham. The 140 fatal cases of whooping-cough were 65 fewer than the corrected average number; among the various boroughs the highest death-rates from this disease were recorded in Chelsea, St. Pancras, Holborn, Stepney, Poplar, Battersea, Wandsworth, Deptford, and Greenwich. The 17 deaths referred to "fever" were 13 below the corrected average number; of these 17 deaths two belonged to the City of Westminster, two to Islington, two to Finsbury, two to Stepney, and one to each of nine other boroughs. The 80 fatal cases of diarrhœa corresponded with the average number; this disease was proportionally most fatal in Finsbury, Shoreditch, Poplar, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was 9 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 115 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Stoke Newington, Holborn, Lambeth, Wandsworth, Camberwell, Lewisham, and Woolwich; and the highest rates in Kensington, Hammersmith, Fulham, St. Pancras, Poplar, and Bermondsey.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Surgeon Francis Edwin McCune has been placed on the retired list (dated Jan. 23rd, 1908).

The following appointments are notified:—Fleet Surgeon F. J. A. Dalton, to the *President*, additional, for R.F.A. *Maine*; Staff Surgeon E. S. Reid, to the *President*, additional, for R.F.A. *Maine*; Surgeon C. T. Baxter, to the *President*, additional, for R.F.A. *Maine*.

ARMY MEDICAL SERVICE.

Lieutenant-Colonel Fitzroy B. Maclean, from the Royal Army Medical Corps, to be Colonel, vice J. F. Williamson, C.B., C.M.G., retired (dated Feb. 6th, 1908).

ROYAL ARMY MEDICAL CORPS.

Major F. M. Maugin has been posted to the Connaught Hospital, North Camp, Aldershot for duty. Captain W. L. Baker has joined at Aldershot and been posted to the Connaught Hospital for duty. Lieutenant M. J. Cromie has been transferred from Mhow to Jubbulpore for permanent duty.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Arthur H. Vernon to be Surgeon-Major (dated Feb. 1st, 1908).

IMPERIAL YEOMANRY.

Lancashire Hussars: Surgeon-Lieutenant J. T. Nisbe to be Surgeon-Captain (dated Jan. 24th, 1908).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Berwickshire: Irvine Kempt Hermon to be Surgeon-Lieutenant (dated Jan. 17th, 1908). 1st Durham; William George Thompson to be Surgeon-Lieutenant (dated Jan. 1st, 1908). Frank Wilfred Burn to be Surgeon-Lieutenant (dated Jan. 3rd, 1908).

Rifle: 2nd Volunteer Battalion, The Prince Albert's (Somersetshire Light Infantry): Arthur Norman Haig to be Surgeon-Lieutenant (dated Jan. 14th, 1908). 2nd Volunteer Battalion, The Welsh Regiment: Surgeon-Major J. A. Jones to be Surgeon-Lieutenant-Colonel (dated Jan. 29th, 1908). 13th Middlesex (Queen's Westminster) Volunteer Rifle Corps: Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel P. P. Whitcombe to be Surgeon-Lieutenant-Colonel (dated August 7th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Western Command: Manchester Companies: Thomas Carnwath to be Lieutenant (dated Jan. 28th, 1908).

TUBERCULOSIS IN THE ARMY.

In the House of Commons on Feb. 18th, in reply to a question by Mr. Summerbell regarding the action which the Secretary of State for War proposed to take with reference to soldiers suffering from tuberculosis, in view of the findings of the Select Committee appointed to go into the matter, Mr. Haldane said that the recommendations of the Select Committee had been recently considered by the Government. The decision was that, however desirable the special provision recommended by the Committee in the case of soldiers discharged from the army because of tuberculosis, it was impossible to justify the assumption of this new kind of obligation by the State unless it is extended to other services as well as the army, and possibly more widely still.

Correspondence.

"Audi alteram partem."

THE LONDON COUNTY COUNCIL AND THE TREATMENT OF SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—You are doubtless aware that the London County Council has caused its Education Committee to appoint a special subcommittee consisting of members of the Council and representatives of outside institutions to inquire into the whole question of the medical treatment of children attending public elementary schools. This subcommittee has been formed and it may be stated at once that the London hospitals, including the Hospitals for Sick Children, are wholly inadequately represented upon it. Under the Education (Administrative Provisions) Act, 1907, the Council has powers to make such arrangements as may be sanctioned by the Board of Education for attending to the health and physical condition of these children. The Education Committee of the Council has issued to the London hospitals a series of questions which indicate the extensive nature of its investigation, the diseases including those of the eye, ear, skin, teeth, malnutrition, &c. There is considerable danger that these questions may be answered without due appreciation of the far-reaching effects of any scheme which may be instituted. It need only be mentioned that school clinics cannot be established without enormous expense and without injury to the hospital clinics; or, if the additional work is thrown upon the hospitals, they will have to bear the increased expense. In the former case, and in the latter also, if the hospitals are subsidised (of which there is no suggestion) the ratepayers will have to practically the same. As regards the third, (c). "refusing to recognise several old-established training schools," the Board has, of course, to exercise its discrimination in this matter, and to refuse to recognise institutions which are in its opinion unsuited for this purpose. But, as there appears to be much misunderstanding on this question, it would point out that recognising an institution is not the only way in which an institution can be utilised for training midwives. The practice of the Board has been to approve an institution as a recognised school of training only when its status is such that it may be taken for granted that none but competent officers of all kinds would be appointed to it.

In the case of an institution, such as one of the great lying-in hospitals, for instance, the Board has taken it for granted that it would be properly officered and its officials are recognised *as such* for the purpose of signing Forms III. and IV. Thus, although officials change, the officials for the time being are recognised; when their connexion with the institution ceases their recognition lapses. On the other hand, in the case of an institution less fully equipped the Board has frequently refused to accept it as a "recognised institution," but has approved its medical officer and midwife for the purposes of training midwives and signing Forms III. and IV. Such an institution, though it lacks the prestige of a "recognised institution," has exactly the same opportunities of training midwives as if its request had been granted. In this case the approval of the medical practitioner and midwife are personal. The Board *has not* received any explanation of the statement that its policy as regards (*a*), (*b*), and (c) "has resulted in an increase in the training fees, and a consequential difficulty *in obtaining suitable candidates*." It *is far from* its wish to produce any such result, but it feels that the standard on which it has so far insisted cannot be lowered with safety to the community.

It must be remembered that nothing but the three months' course of training, with the attendance on 20 labours and puerperia, stands between what may be absolute ignorance and responsibility of the very gravest and most vital character. Only those who have had, on the one hand, to deal with the raw material, and on the other hand with the same material after training and in face of one of the grave complications of childbirth can fully appreciate the extreme importance of making such training, though strictly limited in scope, as thorough and practical as it can possibly be made. To place upon the roll women whose training had in any way been scamped would be to produce a state of things far worse than that which the Act was framed to abolish; for, whereas before the passing of the Act, the name of midwife carried no official weight, since the passing of the Act the name "certified midwife" carries with it the authority of Parliament and implies that its holder has either been adequately trained, or (in the case of a *bonâ-fide midwife*) *has at least avoided conviction for malpraxis* and removal from the roll. The Board therefore feels that its present requirements cannot be safely reduced.

The question of subsidising midwives *is one of extreme difficulty*. It is certain that in some districts midwives are a necessity, yet it is in these very localities that it is difficult for them to earn a living. It is obviously a matter of great delicacy to subsidise a class of persons who are alleged to be in competition with medical practitioners. The Board considers that it must necessarily take some time before an antagonistic attitude can be expected to disappear. In the meanwhile it is of the utmost importance that amicable relations should be encouraged by every possible means, and the Board thinks that this difficulty would be greatly reduced by a scheme by which medical practitioners summoned on the advice of midwives, according to the rules of the Board, could be adequately remunerated. The relations of medical practitioners to midwives vary in different districts; in some they are frankly hostile, the medical practitioners stating that they intend to make it impossible for midwives to practise in their neighbourhood. The Board is not aware of any district in which medical practitioners and midwives coöperate amicably; such districts may, however, exist. It must be remembered that the Board does not receive reports officially on these subjects, and is not in a position to speak with authority. It is possible that a conference could be held with advantage on the subject; if such a conference were held, it would be necessary that it should be thoroughly representative of all interests and that the medical (and especially the rural medical) practitioners should be represented by persons having full authority to speak in their name. The hope of a better understanding must necessarily be preceded by a conviction that "midwives are a necessity" (Report of Select Committee of House of Commons, 1893), and also that midwives, under proper regulation, would act as coöperators and not as opponents. No good would result from such a conference if such delegates were only authorised to demand the abolition of midwives—which might quite possibly be the case.

I am, Sir, your obedient Servant,
G. W. DUNCAN, Secretary.
To the Clerk of the Council, Privy Council Office,
Whitehall, S.W.

A letter from Miss B. M. Worrall, honorary secretary of the Midwives Defence Association, as to the action of the local supervising authority for the County of London in regard to Rule E 26, was further considered. This rule is as follows:—

> The proper designation of a certified midwife is "certified midwife," thus, e.g., Mary Smith, certified midwife. No abbreviation in the form of initial letters is permitted, nor any other description of the qualification.

Memorials on the subject from the Midwives Institute, and from the committee of the British Lying-in Hospital, the City of London Lying-in Hospital, the General Lying-in Hospital, and Queen Charlotte's Lying-in Hospital were considered at the same time, as well as a letter from Dr. H. Scurfield. The Board decided that the Privy Council should be asked to approve the addition of the following words to Rule E 26:—

> *Provided* that a midwife whose name has been admitted to the roll in virtue of having passed the examination of the Central Midwives Board, or in virtue of a qualification under Section 2 of the Midwives Act, 1902, acquired by passing an examination in midwifery, may add the words "by examination" after the words "certified midwife."

Letters were considered from the Master and the honorary secretary of the Coombe Hospital, Dublin, submitting for the observations of the Board certain rules and regulations adopted by the board of the hospital with respect to the training of pupil midwives. The Board decided that the board of the Coombe Hospital should be referred to the public press for the results of the Board's examinations and that subject to the foregoing the Board expresses general approval of the rules.

IMPRESSIONS OF THE FINAL STAGE OF CHRONIC GLAUCOMA.

BY ONE WHO HAS SUFFERED IT.

SOME six years ago[1] I was privileged to give a patient's account in these columns of the exceedingly difficult eye disease known as chronic glaucoma, or grey atrophy, so far as a two years' endurance of it would allow. Having now reached what the doctors consider, and what I also believe, its final stages I venture to give such fuller impressions as my nearly completed experience permits.

At the period in which the article referred to was written it became necessary to make a special maintenance effort, and I accordingly devised a scheme in which two attainments successfully employed in earlier days were included together with my business as a journalist and advertising expert. As a result an engagement was given me by two or three food manufacturing firms, during which I walked some 1200 miles, visiting the principal towns in Lancashire and Cheshire, delivering in places of entertainment, colleges, and schools lectures on the advantages of blindness and of the foods alluded to. The walk was accomplished in July, August, and September, *my 12-years-old son acting as guide*. On most days the evening lecture obliged me to walk in evening dress and a high hat, as there was seldom much time after the day's journey to get ready for the platform. On the whole, the long outdoor exercise seemed to benefit my general health, but it was certainly a considerable strain to grope through unknown buildings and up strange stairways to finally attempt the still more difficult task of interesting an unseen audience, and, if possible, make them laugh. At the conclusion of the expedition there was, in addition to a slight financial gain, an apparent increase in bodily strength, while the gout and nerve pains long suffered appeared to have been got rid of entirely.

A year afterwards, however, the atrophy began to extend over the body, and in January of last year while in the streets I found myself at a full stop owing to a contraction of the leg muscles and had to be carried home to the bed from which I now write. Dr. E. Annacker of Manchester and Dr. J. G. Christie of Longsight attended me and watched the progress of the malady with the skilled practitioner's, and also perhaps the student's, eye. The loss of vitality is apparent in all parts of the body and the nerve pains have returned. Dr. Christie has probed the legs, arms, chest, &c., with a lancet to what he knows would be pain-point in a person of ordinary sensitiveness and has pinched the neck muscles with full force without causing the slightest feeling of pain. Somewhat restless sleep and an appetite apparently ravenous but quickly satisfied, inability to use the legs, and a curious sinking of the nerves as if one of the spasms of a shivering fit had been abnormally prolonged, are the chief peculiarities of my present condition.

Concerning the eyes, there is an increasing in frequency of the phantasmagoria apparent from the first stage of the disease. When the eyes are closed and bandaged and the room is dark a red patch or stage sometimes slightly bordered with a dark blue appears before me. On this surface appear, always coming from the right side, figures, human as well as fanciful, which engage in a kind of kinematograph action. These figures are now invariably speckled with snowflakes, which also cover part of the stage. It requires a strong will and a change of the position of the body to drive away the illusion, if such it be. In thinking the matter carefully out I account for the red stage by the red lining of the eyelid, for the blue fringe by the fact that this is the colour of the eyes, and for the flakes by the jury to retire and consider the verdict. I have stated my case as simply as I could and am content to let it stand as it is—unamended and unqualified.

---

[1] THE LANCET, April 5th, 1902, p. 934.

I am, Sir, yours faithfully,
Wimpole-street, Feb. 16th, 1908. HARRY CAMPBELL.

To the Editor of THE LANCET.

SIR,—I have carefully read and re-read the correspondence between Sir James Barr and Dr. Harry Campbell, and the conclusion I have come to is that it has been greatly confused through a lack of knowledge and precision on the part of the former in discussing the physical problems involved, and on the part of the latter through the use of unnecessarily complicated phraseology.

The employment of the terms "tautness" and "traction" by Dr. Campbell is peculiarly unfortunate, as they, at least it appears so to me, could both have been so much more easily expressed by the word "tension." Tension is a state of strain, or the act of straining, and is a term perfectly well understood. Pulmonary tautness is a pulmonary state of strain, or tension. Pulmonary traction is a pulmonary act of straining, or tension. The word "tension" implies both the condition and the act. The tension of a wire means that it is tight and that it pulls; and it would be absurd to worry over its tautness and traction, as both are stated or implied when one speaks of its tension.

Dr. Campbell says I "*fail to make the necessary distinction* between tautness and elasticity." I purposely avoided discussing the subject, but the distinction is obvious. There can be tension or tautness in a wire far beyond what its elasticity can produce or resist, or there may be tension or tautness less than what its elasticity can produce or resist, in which case the force of elastic recoil or tautness are equal. There can be tension or tautness in a fibroid lung as well as in an elastic one. I am quite at one with Dr. Campbell in distinguishing between tautness (or tension) and elasticity: where I differ is when he says that the negative intrapleural pressure when the thorax and respiratory muscles are at rest "is due to the tautness of the pulmonary tissue pure and simple, and that the factor of elasticity, or elastic recoil, has nothing to do with it." Dr. Campbell, like so many people who discover a truth, fails to see its limitations.

Suppose there be a large pneumothorax; the lung recedes far from the body wall and rests contracted. Gradually, by vital processes, the air is absorbed, and as the chest walls cannot fall in so readily as the lungs can stretch, the latter expand and presently again fill the thorax. What stretched the lungs? Dr. Campbell says "the stretched condition of the pulmonary tissue is effected by the inspiratory muscles." I maintain that the cell action, or other vital processes which actively absorbed the air from the pleural sac, lowered the pressure in it and cleared the space for the lung to expand into, primarily caused its expansion, by decreasing the opposition to the action of the intrapulmonary air pressure. *Likewise though* at birth the lung is stretched by the thoracic expansion, the lung at, say, ten years of age is another lung, and I can conceive of *no other way* in which the new elastic tissue has kept on the stretch than by supposing it has been laid down on the stretch, or has contracted afterwards. In this way the elastic tension producing the intrapleural negative pressure, when the thorax and respiratory muscles are at rest, is *generated within the* lung, and in time would pull the visceral and parietal pleuræ apart if their lining cells would allow air or liquid to accumulate there *and permit their separation*. When the inspiratory muscles expand the thorax beyond the position of rest then it is that they obviously operate *in lowering* the intrapleural pressure.

In addition to his employment of the words "tautness" and "traction" *Dr. Campbell also seems* to me unfortunate in his use of the word "suction." He does not use it as indicating a force decreasing the resistance *to another* force, as Sir James Barr rightly contends he should, but as though it were the force directly producing the effects observed. These are minor *matters; the great* principle for which Dr. Campbell has so earnestly contended—viz., the much overlooked importance of the action of the inspiratory movements in their effects within the chest, and the nature of these effects—he has done much to elucidate and *establish*, and I personally feel much indebted to him for what I have learned at his hands.

In regard to *Sir James Barr's criticisms*, it seems to me, after his letter of Jan. 25th, there is little to be gained by discussing physics with him. He there gives from the "Century Dictionary" a definition of "elastic" in which it is stated, "A body is perfectly elastic when it has the property of resisting a given deformation equally ......," and he remarks: "The Campbell physicist says it is a mere property of a certain form of matter, by which it has the power of recovering its original *form after being* stretched, but I prefer the other authority who says that it also signifies a *resistance to stretching or other deformation*." Now the other authority which Sir James Barr quotes and prefers *does not say* it "signifies a resistance to stretching or other deformation." The words are, "it has the *property* of resisting," and it is this idea of a property which Dr. Campbell and I want Sir James Barr to admit. Surely it would be better if Sir James would "*prefer*" *the definition of elasticity given by the* authority from which he quotes, the "Century Dictionary," rather than his own misquotation from that authority.

Sir James Barr shortly after proceeds in his letter to what he calls "prick the bubble" blown by Dr. Campbell, and he compares the uses of a "non-elastic chain" and what he terms "a hawser made of highly elastic hemp." He says: "The elastic rope offers resistance to being *stretched and* when the tug of *the ship ceases the elasticity gradually pulls* the vessel back to its former position." *Sir James Barr* should know that a hawser is made on *the twist*, and it stretches, not because hemp is what he styles "highly elastic," but because the component fibres and twists *straighten out under tension*, taking a *direction more* along the length of the rope than before and less across it, while at the same time mutually compressing one another. If Sir James twists a piece of *string* he will see that it shortens and will then lengthen when pulled upon more than before. The recoil in the hawser is due to the *recovery of the* parts from mutual compression and has nothing at all to do with elasticity in hemp. Moreover, if Sir James considers hemp *highly elastic, why does he immediately speak* of "non-elastic fibroid lungs"? By what mental process does he make hemp highly elastic and fibroid lungs non-elastic?

Later in his letter Sir James tells how he was selected by the Home Office to "devise a method of estimating the *elasticity of any rope*," and *he modestly says*, "I did not retire to my study and work out the *coefficient* of elasticity, and what should, but probably would not, happen. I determined the *vis viva* or energy which I considered necessary, and then under a strain of a given number of foot pounds I *determined* the stretch, and I had no difficulty in devising a method of measuring the length of unstretched rope which would allow of a *given* energy." Fancy speaking *of* the length of unstretched rope which would allow of a given energy! Energy is the "capacity for doing work," and is measured by *the* amount of *work* a *body* having energy can be made to do. What capacity for doing work is inherent in a piece of unstretched rope. Would it allow *of boiling* a kettle or climbing a hill? It would have been far better if Sir James Barr had retired to his disparaged study and learned the elements of *physics as* taught before hastily experimenting. He might then have started with ideas of energy, elasticity, &c., which were physically precise.

Sir James Barr's criticism in your last issue of my letter of Jan. 25th calls for little comment. He seems to hold me responsible *for* the *consequences* of the physical definition of elasticity. He says: "Let us see how his definition works out." It is nothing to me how my *definition* works out and what confusion or sadness it produces in the mind of Sir James. If he discusses physics as a physicist he *must* take the *consequences, however* they work out; if as the "man in the street" he may call hemp highly elastic, rubber more elastic, and gas most elastic, but he must pose in future as the "man in the street" and not as a physicist. I will leave my last letter and Sir James Barr's criticism of it to the *impartial judgment of* your readers as this communication is already too long, but I hope more particularly that Dr. Campbell's suggestive views *may* have the attention which I think they deserve.

I am, Sir, yours faithfully,
D. W. SAMWAYS.
Mentone, Feb. 17th, 1908.

*** The various parties to this correspondence have had ample space in which to expound their views, and *none of* them can complain of the undue vigour of their *opponents'* language, for none of them has failed to reply with equal vigour. As they cannot all have the last word we supply *it*. This interesting discussion *must* now cease.—ED. L.

half the cases suffering from some form of physical disease for which medical treatment was required. 25 of the cases admitted were over 60 years of age. One of the patients admitted was a woman who had pleaded guilty at her trial for the wilful murder of her two infant children and was sent to the asylum under Section 15 of the Act 25 & 26 Vict., cap. 61. The medical superintendent, in reference to this case, writes as follows: "No opinion is expressed here as to the regularity of the legal procedure followed in this case, but a protest must be raised against what appears to be a growing tendency to make use of asylums as convenient houses of detention for dangerous criminals. The modern asylum is essentially a hospital; its arrangements are not designed to meet the requirements of a gaol, and, in so far as its conditions are made to resemble those of a prison, its efficiency as a hospital must suffer. It is most unfair that respectable members of a community sent to the institution for medical treatment should be forced into association with malefactors and murderers and the presence of such persons in the wards is keenly resented by the patients." 38 patients were discharged during the year, 26 (11 males and 15 females) as "recovered," 11 (six males and five females,) as "relieved," and one woman as "not improved." The recoveries as compared with the admissions give a proportion of 35·1 per cent. (23·4 males and 65·6 females). In 80·7 per cent. of the recoveries the mental disorder was of less than three months' duration on the patient's admission into the asylum. The number of deaths (38) is the highest recorded since the opening of the institution. The rate of mortality calculated on the average number on the register was 11·5 (10·2 males and 12·7 females), but Dr. Johnstone states that examination shows that there is nothing alarming in the high figures, which must be regarded as purely accidental. Pulmonary tuberculosis was present in active form in 28·9 per cent. of the deaths. The medical superintendent draws attention once more to the fact that the legislature has not yet made any provision for the granting of retiring allowances to the staffs of the Scottish district and parochial asylums. Statutory power has been given to grant more or less adequate pensions to the officials of the English county and borough asylums, the Irish district asylums, and the Scottish Royal asylums. Scottish asylum workers have exactly the same kind of duties to perform and they run the same risks as the employees in other asylums. They receive no compensation for the lack of pensions in the shape of higher wages and salaries or otherwise, their remuneration being such as to render it impossible for them to make adequate provision for old age or infirmity; and it is well known that of all public employments asylum service is the most anxious and responsible and the most dangerous to the health of body and mind. The new female wing of the asylum was opened on Nov. 26th, 1906, and the Commissioner in Lunacy, Dr. J. Fraser, states in his report that it is of a highly satisfactory character and suitably and comfortably furnished. He further draws attention in his report to the excellence of the two hospital sections for sick and infirm patients, and to the great advantage that the asylum derives from having four certificated hospital nurses, the matron, the deputy matron, the assistant matron on duty in the male sick ward, and the assistant matron who acts as night superintendent. The present rate of board for pauper patients is £29 per annum. The garden account shows a favourable balance of £189

Leicester Borough Asylum (*Annual Report, 1906–07*).—On Jan. 1st, 1906, there were 815 patients (350 males and 465 females) on the registers of this asylum. The admissions during the year were 221 (85 males and 136 females). Dr. J. E. M. Finch, the medical superintendent, reports that the number of admissions from Leicester itself of both sexes, but especially of males, has been higher during 1906 than in any former year, the admission rate for the previous four years having been stationary. He further adds that should this increase continue more accommodation on the male side will be necessary, though there will be ample room on the female side for several years. Amongst those admitted, insane inheritance was found to be present in 50 instances, intemperance in 21, domestic trouble in 18, congenital defects in nine, and senile decay in 13. During the year 122 patients (57 males and 65 females) were discharged and of these 82 (32 males and 50 females) were considered "recovered," 21 (nine males and 12 females) "relieved," and 19 (16 males and three females) "not improved." In the discharges the percentage of the recoveries on the admissions, excluding those cases transferred from other asylums, is found to be 28·1 in the males and 47·6 in the females. The deaths during the same period were 74 (38 males and 26 females), which gives a rate of mortality estimated on the average number of patients resident in the asylum of 10·9 in the males and 7·3 in the females. The chief causes of death were general paralysis in 13 cases, other cerebral lesions in 12, cancer in three, pulmonary tuberculosis in five, heart disease in 16, and senile decay in eight. Of the 840 patients remaining in the asylum at the end of the year 1906 29 (12 males and 17 females) were deemed to be curable. The total number of epileptic patients under treatment was 128. There were several changes during the year in the staff of the asylum. Amongst the medical officers, the second assistant medical officer unfortunately met with a fatal accident while cycling, and Mr. C. H. Gibson Lyall has been appointed to take his place. Dr. Finch reports many changes among the members of the nursing staff, and the Commissioners note in their report that the duration of service, although as good as in many asylums, cannot be considered satisfactory in view of the fact that 27 per cent. have served less than one year. During the winter the usual lectures on ambulance and nursing have been given, 14 attendants and 19 nurses obtaining the certificate and two attendants and nine nurses the medallion.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Feb. 20th, 1830.

M. CHABERT.[1]

THE following note was received by the EDITOR on Monday last; can any of our Correspondents suggest an appropriate reply? If M. Chabert has no antidote for prussic acid, it is quite evident that he has impudence enough for anything.

"M. Chabert requests Mr. Wakley will give him that satisfaction which is due to a gentleman, for the recent unprovoked, malicious, and unjust attacks against his character."

Saturday noon, Thomas Street,
Waterloo Road, Lambeth.
T. Wakley, Esq., Bedford Square.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8648 births and 5798 deaths were registered during the week ending Feb. 15th. The mean annual rate of mortality in these towns, which had been equal to 18·2 and 18·3 per 1000 in the two preceding weeks, showed a further slight increase to 18·6 in the week under notice. During the first seven weeks of the current quarter the annual death-rate in these towns averaged 18·5 per 1000; the rate in London during the same period did not exceed 18·1. The lowest annual death-rates in the 76 towns last week were 6·0 in King's Norton, 6·9 in Hastings, 7·9 in Hornsey, and 10·2 in Grimsby; the rates in the other towns ranged upwards to 25·5 in Stockton, 25·8 in Rochdale, 26·3 in Merthyr Tydfil, and 31·4 in Yarmouth. The rate in London last week did not exceed 19·0. The 5798 deaths registered in the 76 towns during the week under notice showed an increase of 106 upon the number in the previous week, and included 388 which were referred to the principal epidemic diseases, against 441 and 447 in the two previous weeks; of these, 154 resulted from whooping-cough, 78 from measles, 47 from diphtheria, 43 from diarrhœa, 40 from scarlet fever, and 26 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·2 per 1000, the rate from the same diseases in London being 1·1. No death from any of these epidemic diseases was registered last week in Tottenham, St. Helens, Wigan, King's Norton, or in eight other smaller towns; the annual death-rates will meet with the endorsement of every one who has been a general practitioner and has kept himself abreast of the times and is striving to rise, and with his rise improve the status and prospects of the profession. The first and true definition of a specialist applies to the risen general practitioner, the latter definition applies to the "hospital-appointment-made-specialist" who yet has his knowledge to gain, who has no skill, *yet who professes to sell that which he does* not possess. From the above you can see that the prospects for those who have worked hard as general practitioners is certainly "not much." Your late most honourable campaign in the Law Courts in defence of the rights of the public and of those of us who have to work hard for our daily bread was partly due to the condition of affairs dealt with by both "Virtutem Sequor" and "Half-and-Half."

---

[1] Vide "Looking Back" in THE LANCET of Jan. 18th, p. 172, Feb. 1st, p. 333, and Feb. 8th, 1908, p. 425.

Did general practitioners keep themselves abreast of the times, and were "specialists" (?) more really "specialists" and less "exclusivists" (learning their "one horse-shay racket"), there would be no lay advertisers of this and that "specific" for one disease and another. Is not "specialism" as now practised a species of quackery? A good "general practitioner" is a true "specialist in many departments," a modern "specialist" is a one-string fiddler in an orchestra who does not know his notes. Let me ask "Virtutem Sequor" one question. Is it worse to advertise rather than starve and become a financial defaulter following an unwritten law which no one really cares a straw about, or is it worse to be ethical (with your mouth only), the while doing all you can to hinder and ruin the prospects of your fellow man and brother (?) as is practised in London at hospital elections? Which of the two pictures will show painted the blacker sheep? The frank, open advertiser, according the same to his fellow man, or the hypocrite who does all he can to damn the career of a general practitioner and pitchforks a young "specialist" (?) into a post to keep out the other fellow? All those things of which "Half-and-Half" ably writes have I done, and more. I will therefore finish what he has left unsaid. He says, "It is, I think, forgotten by many that each patient sent by them to a "specialist" means the loss to them, only too frequently, not only of that patient but of all that patient's friends who have, or think they have, any disease affecting that particular region of the body." Let us now continue (in my own words), "and of those who have not, but have ailments of other parts, will that 'specialist' send on direct to his brother 'specialists' in accordance with their custom of mutual 'back-scratching,' and so on, till soon there is no practice left for the general practitioner who sent the first case." If it is borne in mind that these so-called "specialists" are daily engaged in cutting the throats of the lesser general practitioners in the out-patient departments of hospitals, besides distributing their richer patients amongst themselves, we must repeat "*Not much.*" In a recent issue you printed an article showing the existence of a decided schism in the Liverpool district between general practitioners and hospital practitioners who are advertised by their (?) hospital and I make bold to say that the London general practitioner is a greater fool than I take him for if the same does not occur soon in London.

Strangely enough, a letter by "F.R.C.S." entitled "The Responsibility for the Anæsthetic" shows up another phase of the "prospects of the profession." Why does the general practitioner asked to be allowed to give the anæsthetic? As one who has been a general practitioner let me answer. To be able to retain a hold on his patient, as a patient, and not to be entirely cut out of that which his honesty has put into the hands of "F.R.C.S." A general practitioner nowadays is a tout (at his own expense), paying his rent, rates, taxes, and keeping up a position, purely in order to find cases with fat fees for the "specialist." The "specialist" comes in, whisks the patient off to a nursing home, and out goes the poor wretch of the general practitioner to his debts; those that he owes and those that are owed to him. In nine cases out of ten, the general practitioner has money owing to him by the patient for present and past illnesses, the "specialist" comes in, and the patient begs, borrows, or steals the wherewithal to pay the fee demanded. Off goes the specialist with the "ready" and the general practitioner has only debts owing to him, and a useless patient for some time to come, till the money borrowed to pay the "specialist" is repaid. "I have had some" and got heartily sick of it. The more fair and equitable rule is the one which I now follow, and perhaps "F.R.C.S." will please note and practise it. When the case needs operation my practice is as follows: refuse the request except the general practitioner be a skilled anæsthetist, but ask the general practitioner to assist at the operation and undertake the major part of the after attendance, and for his services give him "down on the nail" one-third of the fee agreed upon for the operation, for he has earned it. So that "F.R.C.S." can still have his skilled anæsthetist and at the same time feel that the general practitioner gets something for his wife and children and is not left, as he often is, a "skinned eel" with an "invitation to dinner." More often than not that third part of the operation fee will be the only money the general practitioner will ever see out of the case. Let this plan be adopted universally and there will then, at any rate, be some prospects for both general practitioner and specialist. Mutual help and support should be the watchword, not selfish hindrance and throat-cutting, grasping greed.

I am, Sir, yours faithfully,
F. W. FORBES-ROSS, M.D. Edin., F.R.C.S. Eng.

Harley-street, Feb. 16th, 1906.

To the Editor of THE LANCET.

SIR,—So far as the general public is concerned "Virtutem Sequor" raises a very important issue in his remarks *re* consultants. What constitutes a consultant, and to what fees is he entitled? A friend of mine afflicted with failing eyesight had occasion to go to an optician who advised him to go to a certain oculist. This latter gentleman examined the eyes, prescribed glasses, and charged £2 2*s.* On subsequently referring to the Medical Directory it was found that the doctor consulted had merely ordinary qualifications and was not, nor ever had been, attached to any ophthalmic hospital.

Now, Sir, as a mere layman, what I want to know is, how can the public be protected from this kind of thing? The general impression amongst us is that a consultant is a gentleman of the highest qualifications (e.g., F.R.C.S.) and who has a hospital appointment. I appeal to you, Sir, for an *ex cathedrâ* pronouncement on the matter.

I am, Sir, yours faithfully,
Feb. 14th, 1906. WALTER CARTER.

THE INACCURATE DOSAGE OF MEDICINES.

To the Editor of THE LANCET.

SIR,—Your remarks in an annotation in your issue of Feb. 15th, p. 512, on "The Inaccurate Dosage of Medicines," due to the different sizes of bottles supposed to be two, four, six, and eight ounces, are most appropriate, but there is also, I think, a still greater reform required, that all tinctures should be so prepared that the same quantity of each should represent an adult dose, say one drachm. Infusions might be one ounce, wines one drachm, and so on, with spirits, pills, powders, &c. Surely wholesale druggists could arrange this, and so reduce the dangers and difficulties in dispensing medicines. There is often some uncertainty in remembering the correct doses of drugs other than those habitually used, and a desirable preparation may be omitted from the prescription through this cause.

I am, Sir, yours faithfully,
Dorney, Windsor, Feb. 16th, 1906. J. H. WATERS.

RECEPTION HOUSE FOR RECENT CASES OF INSANITY.

To the Editor of THE LANCET.

SIR,—Through the medium of your valuable columns and the columns of your less specialised contemporary the *Sunday Chronicle*, I have recently learnt that some striking "advances" have been made in the treatment of mental diseases in Scotland—namely, (1) through the medium of a structure of corrugated iron and "compo" boarding, &c., and (2) some open air.

I regret that (owing possibly to a defect within myself), having carefully read all the details mentioned in Dr. H. C. Marr's paper in your issue of Feb. 8th, I entirely fail to see, on analysis, any difference in the practice adopted at Woodilee to that in use here (in the southern portion of England) for many years, or in probably 90 per cent. of other asylums in England, with the exception that: 1. Only few asylums have female nurses in the male wards, and this may, or may not, be an important factor, though I personally have yet to feel that yearning desire to add one to the female staff. 2. That

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JANUARY, 1908.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1908.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE report of the Principal to the governors of the University, which was presented at the annual meeting on Feb. 20th, shows a large increase in numbers in the Faculties of Arts and Science, and as satisfactory a condition as could be expected in the other faculties. Medicine and commerce remain comparatively stationary, and the numbers in the Medical Faculty are not likely to increase till the rush into engineering declines and the public recognise that, for the money and time spent, the medical profession offers as good a return as, if not a better average return both as regards money and position than, any other profession. In medicine as in other professions it is true that there is always plenty of room at the top, but it is more true of medicine than perhaps of any other profession that the licentiate or graduate from the moment of obtaining his qualification or degree can make a respectable living. This simple fact is not generally understood and until it filters into the minds of parents and guardians the number of entries in the Medical Faculty is not likely to increase largely. As regards the University as a whole the Principal's report shows that its work is proceeding satisfactorily and advances are being made, but further extension and development are hampered by want of funds. This is a condition which afflicts most of the universities of England but it is particularly felt in Birmingham where the advances have been so rapid and great in a comparatively short time. Money is urgently needed and it is to be hoped that before long it will be obtained, so that the excellent work going on may proceed steadily and without hindrance.

Mr. J. Hall-Edwards.

Every member of the medical profession, as well as his own immediate friends, will sympathise with Mr. J. Hall-Edwards, whose left hand was amputated at the beginning of the week. Mr. Hall-Edwards was an enthusiastic pioneer of x ray work and his hand is a sacrifice to the advance of medical science, for, prosecuting research in the new avenue of work before the dangers were understood, he exposed himself fearlessly to the rays and, unfortunately, his hands were attacked with x ray dermatitis. Treatment failed in the case of the left hand and as the condition was proceeding from bad to worse it became necessary to amputate, but it is hoped that the right hand will respond to treatment and that no further operation will be necessary.

The University Company of the 1st V.B. Royal Warwickshire Regiment.

The annual dinner and prize distribution in connexion with the above company, which took place on Feb. 14th, was, in a certain sense, not devoid of gloom, for there was a fear which expressed itself, even through words of hope to the contrary, that the members might be taking their last annual dinner together as a university company. What is to happen to university companies under the new scheme of re-organisation is not yet known, for, as Mr. Neville Chamberlain said, the wheels of the Government move slowly in this matter, but it is clear that unless some special provision is made the days of university companies are numbered. They cannot form part of a local battalion because the terms of enlistment, &c., are not compatible with university duties. It is possible that they may be affiliated with a local battalion and therein lies the hope of many, but it is feared that they may be disbanded, in which case much valuable material will be lost.

Medical Inspection of Schools in West Bromwich.

The report of the West Bromwich elementary education committee on the medical inspection of school children is interesting both as regards the estimate of the work to be done and the price it is proposed to pay for it. The committee estimates that there will be 1500 children admitted since January 1st who will have reached the age of five years. These will have to undergo a thorough and searching examination, and there is to be a second examination of 1500 children who will be leaving during the year. When the scheme is in full working order there will be in addition two intermediate examinations. The committee's report states that the medical officer estimates that 800 hours per year will be required for the examinations. Apparently, therefore, when the scheme is in full working order, 6000 children will be examined each year in 48,000 minutes, and it is clear that there will be no excess of time for thorough examination. The cost is estimated at £350 for the first year and it is suggested that a medical inspector should be appointed at a salary of £250, the remuneration to cover expenses and any extra personal assistance.

The Notification of Births Act.

The Birmingham city council has adopted the Notification of Births Act (1907) and it is to come into force on March 1st next. In view of this fact the medical officer of health has sent a letter to all practitioners in the city area drawing their attention to the fact that on and after the date mentioned, in the case of all children born after the twenty-eighth week of pregnancy the birth must be notified either by the father or by the person in attendance upon the mother. The medical officer points out that all births must be notified irrespectively of class, but it is, of course, understood that the health visitors will only be sent to those cases where it appears that their services may be useful. Forms of notice have been printed and a supply of them can be obtained on application to the health department; they are, however, not essential, and a post-card or letter will serve the purpose equally well.

The Health of the City.

Coincidently with the period of sudden changes of temperature which came upon us last week the death-rate of the city has jumped up from 18·6 to 21·7. The increase is almost entirely attributable to pulmonary affections which are so liable to become serious under the conditions mentioned. We are also suffering from an influenza epidemic, but though it is widespread it is, on the whole, a mild attack and so far has proved fatal only in a comparatively few cases. It is, however, proving a serious trouble to many large business establishments whose staffs it has decimated severely.

Health of Sutton Coldfield.

Sutton Coldfield may almost be looked upon as a residential part of Birmingham, for so many of those who spend their days in the city live during the remaining parts of their lives in this very healthy borough. In his annual report on the sanitary condition of the borough, Dr. A. Bostock Hill estimates that the population has increased by 1054 during the year and that it now totals 20,000. The birth-rate for the past year was only 19·71, the lowest recorded since 1898, and the death-rate was 8·97, which is the lowest for the last ten years. Being so easily reached and so healthy it cannot be a matter of surprise that so many people who make their livings in Birmingham choose to reside in Sutton Coldfield.

Feb. 18th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Meat-Traders' Conference.

AN important gathering of delegates from all parts of the country met in Manchester last week to attend the annual meeting of the National Federation of Meat Traders' Associations. In his presidential address the chairman mentioned that the members of the trade were handicapped by laws and enactments administered by men "who had plenty of theory but no practical knowledge." He spoke also of the confusion and want of uniformity with regard to the inspection of meat, scarcely two places being alike in this respect, so that meat may be passed as fit for consumption in one place while at another 30 miles away the same meat would be condemned. No doubt uniformity is desirable and inspection should not be needlessly vexatious, but it is necessary for the protection of the public that it should be thorough. On one matter meat-traders have always shown great sensitiveness and wrathful indignation—namely, on what the President called "the exaggerated statements about private slaughter-houses." He reproved the *Manchester Guardian* for calling them "vile places, insanitary places, dirty places, and they were given a very bad character." On the other hand, he said the "owners of private slaughter-houses are animated by a love of cleanliness and sanitation, and are not afraid of the inspector's visits, because they take a pride in their buildings and their trade." This is no doubt true of large numbers of meat-slaughterers, let us hope of the majority, but the residuum has to be looked to, and that there is such a residuum the annals of bear the burden. Judging by the examination of school children for diseases of the eye, which is already in force, no attempt will be made to ascertain whether the parents are in a position to pay, however inadequately, for advice. If the scheme is extended to include diseases of the skin, general debility, &c., general medical practitioners must inevitably suffer severely.

I have been led to trouble you with this letter more particularly on account of the false analogy which is likely to be made between special diseases, such as diseases of the eye and other complaints. It has already been pointed out in your columns that the work now done by the County Council oculists might equally well be done by teachers after a short course of instruction, and you have advocated that the oculists should correct the refractions which at present they are occupied in discovering. I am in complete agreement with this policy which would relieve hospital clinics of uninteresting drudgery and would entail no hardship upon general practitioners. It is a very different matter, however, to hand over to the County Council the treatment of other minor complaints and more serious diseases affecting school children, for this would be in the highest degree detrimental to hospital clinics and general practitioners, as well as entailing enormous expense.

More than ever at the present time questions continually arise which demand coördinated action on the part of the medical staffs of the London hospitals. Lack of coördination in matters such as that under consideration is likely to lead to schemes which fall short of the best which can be devised. In this manner the praiseworthy aims of the County Council and of the hospitals, which are alike working for the alleviation of suffering, are liable to be frustrated. The lay control of the London hospitals is in some considerable degree coördinated by the Council of King Edward's Hospital Fund. I would suggest that a standing committee composed of representatives of the medical staffs of the London hospitals be formed to which matters of mutual interest might be referred with a view to coördinated action. The Central Hospital Council does not exactly meet the requirements of the case.

I am, Sir, yours faithfully,

Wimpole-street, W., Feb. 15th, 1908. J. HERBERT PARSONS.

DEVELOPMENT OF NODULES IN SUTURE SCARS AFTER OPERATIONS FOR THE REMOVAL OF CANCER.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 1st Mr. C. W. Mansell Moullin, in a paper on the above subject, draws attention to cancer nodules occurring in the cicatrices caused by the sutures used in closing the abdomen in a case of cancer of the pylorus which had been under his care. In referring to a publication of mine in THE LANCET of Nov. 9th, 1907, in which somewhat similar cases were reported, he considers that the appearance of nodules in his case suggests that the mode of conveying cancer infection to the suture tracks is not so simple as is generally believed. My paper referred to the danger of cancer infection and its importance in relation to the question of "recurrence." I tried to demonstrate that the cancer cell is infective, and therefore if it be set free at the time of operation it is liable to be implanted by the surgeon or else implant itself in some part of the wound and thus give rise to a fresh cancerous outbreak. The cases of suture scar nodules quoted were given as illustrations of how readily cancer cell implantation may occur and also as some of the possible ways in which implantation may be brought about.

In the course of my experience I have come across a great many varieties of infection of the suture tracks: in some the infection was limited to the superficial and in others to the deeper layers of the skin; and, again, it manifested itself as a nodule deeply in the tissues directly in the course of the sutures; and I have also seen it occurring as infection of the entire track of the suture; nevertheless, it is far from belief that these cancer "recurrences" were all due to infection having been carried there on the needle or sutures. In Mr. Mansell Moullin's case two sets of sutures were used in closing the wound, one of stout catgut, interrupted, passing through all the layers of the abdominal wall except the skin; the other of finer catgut, continuous, through the skin only. Practically all the suture points of the former series were infected; none of the latter. His explanation as to how the latter condition occurred appears to me to be a perfectly rational one, and I may add that a similar condition has come under my own observation. The fact that no nodules appeared in the scars of the superficial stitches leads one to infer that there were no free cancer cells at the time of operation and that the infection in the tracks of the deeper sutures came from the abdomen. Cancer cells escaped where the sutures pierced the peritoneum, and finding their way along the tracks there they became lodged, and probably the tissues damaged by the suture proved themselves a ready site for implantation. Where the abdomen is closed by a single row of "through and through" sutures the infection will sometimes spread along the whole suture track, and, in fact, in cases of tubercular disease of the peritoneum, tubercular infection spreads in a similar way along the suture. Doubtless Mr. Mansell Moullin's suggestion explains the occurrence of these phenomena. On the other hand, his explanation of the occurrence of cancer nodules in suture scars, after operations for mammary cancer, is a totally different one. He suggests that cancer cells may be present in the tissues, and that the irritation of the sutures may cause these cells to take on greater activity at the points of irritation, hence the subsequent development of suture scar nodules. Though I recognise the possibility of this, yet I very much doubt that it is a frequent occurrence.

It is a recognised fact that the peripheral spread of mammary cancer is almost entirely by the lymphatics. Therefore, if cancer cells are present in the tissues of the flaps it almost necessarily follows that infected lymphatics must have been divided at the time of operation, thus allowing the escape of cancer cells. From my experience these latter would very readily manifest themselves by setting up cancerous infection along the line of incision, if they did not even cause widespread infection of the whole wound. It is not so much that cancer cells are already present and that they take on activity owing to diminished resistance of the tissues as the result of irritation of the sutures, which is mainly the cause of suture scar "recurrence." Our own faulty technique is more frequently responsible. It permits the escape of free cancer cells, which readily implant themselves in whatever part of the wound they may come to rest, or to whatever part of it they are carried by the surgeon, whether by suture or otherwise. This explains many of the cases of suture scar infection, but there are others, and Mr. Mansell Moullin's interesting case is one of these, where the suture does not actually carry infection; but, on the other hand, it encourages or permits of ready implantation.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 11th, 1908. CHARLES RYALL.

PLEURAL EFFUSION AND ITS TREATMENT.

To the Editor of THE LANCET.

SIR,—In my letter in THE LANCET of to-day, *p.* 521, *col.* 1, second line, "not elastic" should be "non-elastic"; p. 522, col. 2, twentieth line, "abstract quantity" should be "abstract quality." I would not have troubled about these trivial mistakes only I am dealing with two *soi-disant* philosophers and I don't wish even a printer's error to creep into my letter.

I am, Sir, yours faithfully,

Liverpool, Feb. 15th, 1908. JAMES BARR.

To the Editor of THE LANCET.

SIR,—You have been so generous with your space that I forbear to reply categorically to Sir James Barr's last letter, the more so that a detailed reply would involve much repetition and probably weary your readers. That Sir James and I differ profoundly on the subject of pulmonary physics is becoming more and more obvious. Sir James now asserts that the tautness of the lungs does not exert traction, that the pulmonary tissue is *not* relaxed at the end of a full respiration, that the fibroid apices of the lungs in fibroid phthisis do not drag in the chest walls, and that, no matter how many of the pulmonary vessels are destroyed in this disease, if "*taut lungs constantly maintained a negative intrathoracic pressure there could be no obstruction to the systemic venous circulation.*" (Not even if all the pulmonary capillaries were reduced to a single one!) In my opinion all these contentions are wrong.

It seems to me, Sir, that the time has now come for the

Aberdeen Royal Infirmary along with the accounts, &c., for the year ending Dec. 31st, 1907, has just been issued. The average number of beds in daily occupation was 226; average number of days in hospital of each patient, 26; operations performed, 1689; and death-rate, 6·9 per cent. in cases treated. The number of in-patients treated (3119) shows an increase of 281 over that of 1906. 15,792 out-patients (including 1606 treated in the electrical department) received advice and treatment. The average cost per occupied bed is £53 9*s*. 2*d*. and of each in-patient £3 17*s*. 6*d*., as compared with £50 3*s*. 7*d*. and £3 19*s*. 7*d*. respectively for the year 1906. A gift which afforded much gratification was the cheque for £10,000 received from the Right Hon. Lord Mount-Stephen towards the endowment fund. A further addition to this fund was received in the form of a donation of £300 made by the trustees of the late Miss Helen Walker from the residue of her estate. The nursing staff consists of nine sisters and 60 nurses. The candidates for admission numbered 378. Under an arrangement with the governors of the Aberdeen Educational Trust the nurses have had the advantage of a course of instruction in invalid cookery. The days for the admission of patients' friends have been arranged as follows: (*a*) For residents in Aberdeen, Wednesdays and Saturdays from 3 to 4 P.M., and Sundays from 4 to 5 P.M.; and (*b*) for country visitors, every weekday from 3 to 4 P.M., and Sundays from 4 to 5 P.M. At the convalescent hospital 206 cases were treated during the year, the average period of residence being 33 days. The income amounted to £445 and the expenditure to £612. Reference is made in the report to the death of Mr. William Carnie who for the long period of 37 years—from 1861 to 1898—occupied the office of clerk and treasurer to the Royal Infirmary and the Royal Asylum.

Feb. 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Tuberculous Disease in Ireland.

AS returned in the last quarterly return of the marriages, births, and deaths in Ireland the total number of deaths from all forms of tuberculous disease registered during the quarter was 2418, representing an annual rate of 2·21 per 1000 of the population of Ireland, estimated to the middle of the year. The rates for each of the three preceding quarterly periods for deaths from all forms of tuberculous disease were 2·76, 2·97, and 2·24 per 1000. The above total—2418—constitutes 13·4 per cent. of all deaths registered during the quarter.

The Health of Belfast.

For the week ended Feb. 8th the death-rate from all causes was the terribly high one of 27·8 per 1000, and from the principal zymotic diseases 3·7. During the week there were notified two cases of typhus fever, four of typhoid fever, 11 of scarlet fever, seven of diphtheria, and eight of cerebro-spinal meningitis. There were (on Feb. 19th) in Purdysburn fever hospital 76 patients. Of these, 21 were suffering from cerebro-spinal meningitis, which the city corporation has decided shall be a notifiable disease for one more year dating from Jan. 1st, 1908.—A deputation of ladies representing the executive of the Belfast branch of the Women's National Health Association of Ireland appeared before the public health committee of Belfast in reference to the aid which they might give in the infantile mortality question. The health committee promised to supply report cards similar to those in use in the health department.

Feb. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Comparative Influence of Intestinal Juice upon Pepsin and Pancreatin.

M. Loeper and M. Esmonet made a communication to the Society of Biology, at a meeting held on Feb. 1st, on the above subject. They had found by experiment that the activity of pepsin diminished by three-quarters under the influence of duodenal juice, by one-half under that of the juices of the ileum, and by a quarter under the influence of the juices of the colon. On the other hand, the activity of the secretion of the pancreas *increases* as regards the power of the trypsin, the steapsin, and the amylopsin in the same proportion for the various regions of the intestine.

The Meal (Farine) of Netté.

Various explorers have noted that the "*farine de Netté*" produced from the fruit of *Parkia biglobosa* is a form of nourishment much appreciated by the natives of tropical Africa; despite its name it is not a meal, for it contains no starch. It is, however, very rich in fat, in phosphates, and in sugar. At a meeting of the Academy of Sciences held on Jan. 27th M. Goris and M. Crété communicated a paper in which they gave the results of some researches which they had made into the alimentary value of this foodstuff. Analysis showed that it was the richest in saccharose of any food which they had come across. Beetroot pulp, for instance, contains from 18 to 20 per cent. of saccharose, and sugar-cane an almost similar proportion, but the substance under investigation contains as much as 25 per cent.

The Hygiene of Dwellings.

Some years ago M. Juillerat, the chief of the Bureau of Hygiene of the Prefecture of the Seine, took up the question of the sanitary arrangement of all the houses in Paris. A new campaign has just been entered upon by the "Ligue Sociale des Acheteurs." This society, which formerly dealt with insanitary houses and the lodges of *concierges*, is now directing its attention to the conditions under which servants are housed. Its members bind themselves only to become tenants of those flats where the rooms allotted to the servants are provided with windows affording proper ventilation and light and where there is a proper apparatus for warming. A list of houses fulfilling these conditions will be drawn up and it will be open to public inspection.

The Treatment of Disease of the Hip-joint by Intra-articular Injections.

At a meeting of the Academy of Medicine held on Feb. 4th M. Calot discussed Hip Disease and held a brief for the great superiority of the method of treatment by injection over any cutting operation or simple immobilisation. He claims that it shortens the length of time necessary for treatment by two-thirds and brings about a cure without lameness or even shortening the limb. The treatment is practically identical with that of a cold abscess. If there is no effusion iodoform injections may be used, or still better a solution of naphthol-camphor in glycerine. M. Calot has been using this method of treatment since 1893.

The Thyroid Treatment of Chronic Rheumatism.

At the same meeting of the Academy M. Léopold de Lévi and M. Henri de Rothschild communicated a paper dealing with 39 cases of chronic rheumatism in patients of both sexes, aged from 12 to 15 years. 10 of these cases were of generalised chronic rheumatism, while 9 showed the nodular form with ankylosis and persistent pain. Out of these 19 patients 14 improved greatly, while 2 could be considered as cured. Of the 20 remaining cases who showed the disease in a milder form, 18 improved or were cured. The treatment consisted in the administration of 10 centigrammes of extract of sheep's thyroid from one to three times a day. The effects of the treatment must be carefully watched.

The Poison of Koch's Bacillus Tuberculosis.

At a meeting of the Academy of Sciences held on Feb. 10th Professor Armand Gautier brought forward some researches undertaken by Dr. Auclero and Dr. Paris on Koch's bacillus tuberculosis. These observers found three distinct poisons in the bacillus—namely, a tuberculin, lecithin, and a special protoplasm poison. This last can be separated chemically and a quarter of a milligramme of it will slowly kill an average-sized guinea-pig by bringing about the same conditions in the lungs as does the bacillus itself.

Arsenic in the Treatment of Syphilis.

At a meeting of the Therapeutical Society held on Jan. 18th M. Bardet put in a strong plea for the use of arsenic in cases of syphilis where mercury is ill borne. He was anxious that the treatment should be tried in hospital, and as he considers that in some cases of syphilis arsenic has a specific action he said that it ought to be tried by itself and not in combination with mercury or the iodides. In the town he thought it would be better given by injection, but in the country, where there might be a difficulty in the

TOMB OF AN ANCIENT EGYPTIAN PHYSICIAN.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 11th in your annotation on "The Burial Customs of Ancient Egypt" by Professor John Garstang you mention the following in connexion with the deceased physician's tomb—viz., that "various and many as were the objects deposited beside his body only two of these can in any way be considered as connected with his vocation—namely, a set of writing implements, consisting of a writing tablet and a pen-box"; also that "unfortunately no written notes survive upon the palette." The significance of the pen box and tablet in or upon the tomb seems to be misunderstood. They are not scarce in any of the bigger towns of India and Arabia. Those who have visited the well-known tombs of the Moghul Emperors, Akbar and Shah-Jehan, and their wives, must have noticed the carved pen box and the adjacent tablet, these being purely symbolic, the pen for the man—the active agent and doer of things; the unwritten slate representing the woman—i.e., the passive agent, the slave and complement of the man.

I am, Sir, yours faithfully,
L. JONES, M.R.C.S. Eng., L.R.C.P. Lond.

Sialkote, India.

THE SITUATION AT THE HAMPSTEAD GENERAL HOSPITAL.

To the Editor of THE LANCET.

SIR,—I think the time has come when an attempt should be made to remove the impression that this hospital has been guilty of some crime against society in general or the medical profession of Hampstead in particular, and in order to do this I beg the hospitality of your columns, although in telling the story I am largely repeating what has already appeared editorially in your columns.

The Hampstead Hospital was started in 1882 with a few beds for patients able to contribute a little towards their support, and was most successfully officered by certain general practitioners in its neighbourhood. It is misleading, however, to describe it as a "cottage hospital." The free beds, which have existed since 1894, have always been in charge of the regular medical staff; only the "contributory beds" have been available to other practitioners. In the new hospital there is no intention of taking away this privilege from the local members of the profession.

As a result of increased demands the first portion of the new hospital was erected two years ago with 64 beds, and in these excellent quarters the hospital has continued to receive the willing and able services of the same staff of general practitioners. At the opening ceremony it was announced that a sum of £10,000 was required to free the hospital from debt and that a further sum of £15,000 would complete the scheme to provide a total of 110 beds. An immediate response was received, Sir Henry Harben announcing that he was authorised by an anonymous donor to say that £20,000 would be forthcoming if the remaining £5000 required were obtained. To avoid diverting support from the general funds of the hospital by an appeal for this sum the council laid the conditions of this special offer before King Edward's Hospital Fund and received a promise from them to provide the sum of £5000. At the same time the King's Fund suggested that the growing importance of the hospital made it desirable for it to adopt a similar constitution for its medical staff to that of all other general hospitals in London.

At a later date the King's Fund having had its attention drawn to the condition of the North-West London Hospital, the buildings of which were considered unfit for continued treatment of in-patients, and the committee of that institution being unable to see its way to obtain an adequate sum for rebuilding, suggested that an amalgamation of that hospital with the Hampstead General Hospital might be arrived at, an out-patient department being maintained solely in Kentish Town and all in-patients being received at the Hampstead Hospital. The King's Fund decided that as it was proposed that the Hampstead General Hospital should henceforth be reckoned, as was the North-West London Hospital, amongst the Metropolitan hospitals, it should be a condition of the amalgamation that the Hampstead General Hospital should be officered by physicians and surgeons of recognised consulting rank. In a canvass on this proposal, by means of a series of questions issued to the members of the local profession, the opinions expressed for and against the change were almost equal, but the result was distinctly unfavourable to the scheme of a mixed staff of general practitioners and physicians and surgeons in consulting practice. It was eventually resolved by the council of the hospital to make the change to a staff consisting of physicians and surgeons in consulting practice, with definite provision for a term of continued service in the case of members of the existing staff of general practitioners. *These terms were accepted as satisfactory by the members of the existing staff*, except as regards the decision, arrived at later under the amalgamation scheme, that the two junior members in charge of out-patients (being in general practice), who were entitled to further service of 13 years each, should not be eligible for promotion to in-patient posts.

As regards the amalgamation proposals, I may say that on April 10th, 1907, a committee of the local medical profession and the medical staffs of the Hampstead and North-West London Hospitals reported to a meeting of the British Medical Association (Hampstead division) that the proposed amalgamation with the North-West London Hospital was desirable from the public point of view (on certain conditions). On the amalgamation being decided upon, the medical staff placed themselves in line with the local practitioners who were opposed to the changes. Since then, as your readers are aware, a canvass of local practitioners has been made by the Hampstead division of the British Medical Association, resulting in a vote which in their view justified their sending a "warning notice" to the *British Medical Journal* which was accepted.

I may say that the council of the hospital appreciate most highly the valuable services of the present acting medical staff and also their generosity in consenting to act until successors could be appointed; but the council nevertheless much regret that when arrangements had been made for the retention of these gentlemen on the staff, on a plan but slightly modified from that which had been approved by them, they should suddenly have changed their mind and *joined with others in a scheme for preventing their place being filled by such persons as the King's Fund suggested*, and financial reasons had compelled the council to accept. The hospital cannot get the promise of the necessary financial support in Hampstead—it will need three times as large an income as that which it has been able to count on—and it has no alternative but to accept the substantial and welcome help offered by the King's Fund, and at the same to submit to its conditions which, after all, in a place like London, are not unreasonable.

In conclusion, I would say that the council of the hospital have no quarrel with the medical profession in Hampstead, nor, on the other hand, have they any fear, doubt, or hesitation in adopting the course which the successful evolution of the hospital has thrust upon them.

I am, Sir, yours faithfully,
ERNEST COLLINS,
Chairman of the Council, Hampstead General Hospital.

Hampstead, Feb. 19th, 1908.

THE PRESENT PROSPECTS OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—Continuing on the ethical lines which we as a profession have been following the answer to the heading of this correspondence would be, "Not much." The letter of "Virtutem Sequor" contains much which can be agreed with, particularly that part in which he deals with so-called "specialists." Some while ago you headed a correspondence, "What is a specialist?" To this question you had replies but no definition. I will, with your kind permission, essay that needed definition. "A specialist in a department of the healing art is one who, knowing thoroughly the entire human body and its ailments, is able to devote his attention to that department for which his skill and dexterity are most suited." Instead of the above, "specialism," as now practised, should be defined as follows: "A 'specialist' is a person whose knowledge needs increasing and skill perfecting in that department in which he exclusively practises, presuming upon a superficial knowledge of the human body and its ailments generally." The contrast is as striking as true. The letter of "Half-and-Half" centres the "bull's-eye" and methods of acute observation and exact diagnosis. In his work on the infectious diseases of childhood and in his investigations on the treatment of rickets his knowledge of the complicated conditions of the growing organism is clearly illustrated. Professor Frühwald was director of the children's department of the Policlinic since 1891 and his lectures were attended by numbers of medical men from all countries, whilst his consulting-room was the meeting place of parents belonging to all classes of society. His health had been giving cause for anxiety since last summer. He had an attack of uræmia six months ago, and kidney trouble led on to cerebral hæmorrhage which finally proved fatal.

Cholelithiasis in Children.

At a recent meeting of the Medical Society Dr. Friedländer showed a boy, six years of age, who had from his second year suffered every few weeks from colic lasting for one or two days. When he passed solid motions these attacks ceased. Later a tumour was made out in the right hypochondrium and as vomiting occurred cholelithiasis was suspected and an operation was performed. The gall-bladder was enormously distended but no reason for the distension was discovered. A year later laparotomy had to be performed again. This time a large calculus was found in the cystic duct. The gall-bladder was removed and the patient was now doing well (ten months after the operation). As regards the earliest age at which cholelithiasis has been known to occur, Dr. Friedjung said that he has seen a biliary calculus in an infant four weeks old, but the condition must be very rare in children, because a case is hardly ever seen in the post-mortem rooms. Professor Naunyn believed that biliary calculi were not uncommon at the age of six years.

A Safe Method of Opening the Abdomen.

At a meeting of the Gesellschaft der Aerzte Professor Lihotzky explained a method of opening the abdomen which was new here although much in vogue in Germany and for which it was claimed that it gave an excellent functional result with a minimum of local disfigurement. It was called the suprasymphysic transverse section of the fasciæ. The incision was from three to four inches long, slightly curved, and extending transversely over the pubes, dividing the skin, subcutaneous tissue, and fasciæ. The latter were then detached from their base upwards and downwards so that the recti and pyramidales muscles were free. The recti muscles were then divided in a longitudinal direction so that they were held only by a thin layer of connective tissue and the transverse fascia and the peritoneum were subsequently incised. This method gave a very ample access to the abdominal and pelvic organs. Tumours reaching up to the umbilicus could be easily removed through the opening. All operations on the uterine adnexa as well as the total extirpation by Wertheim's method and the operative treatment of extra-uterine pregnancy could be easily performed. The closure of the wound was effected in the following manner. The peritoneum and the recti muscles were sutured in the longitudinal direction and the fasciæ and skin in the transverse direction. The sutured wound was covered with gauze, held down by two strips of adhesive plaster. After eight days the sutures in the skin were removed, after which the patient might be out of bed without any abdominal belt. The cosmetic defect of the scar was soon concealed by the hair growing over it, especially if the incision was not very large, whilst the transverse scar was not liable to become stretched with formation of ventral hernia. This functional superiority of the horizontal incision over the vertical one has been proved by many hundreds of cases in Germany and also in Austria. The method was also available for a bilateral Bassini operation if the angle of the incision was drawn well to the side by means of a blunt hook.

Excision of a Pad of Fat from the Abdominal Wall.

Professor Eiselsberg had recently under his care a man, 25 years of age, a waiter, who was not able to sit down on account of the fat on his abdominal wall. The patient's general conformation presented a juvenile type. All the epiphyses were in loose connexion with the diaphyses, the genital organs were infantile, and there was extensive lipomatosis. As the accumulation of fat was a hindrance to the patient in his occupation he was operated upon with a view of removing as much as possible of the superfluous tissue. Within 15 minutes six kilogrammes (13 pounds) of fat were removed and the patient had an uninterrupted recovery. This was the largest amount of fat intentionally excised of which there was a record where general lipomatosis was the indication, but in operations for hernia even larger quantities have been removed.

Feb. 17th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Industrial Accidents in 1907.

SINCE the coming in force of the Workmen's Compensation Act the necessity of exhaustive accident statistics is felt more and more. Francis Kossuth, Minister of Commercial Affairs, has endeavoured to fill this gap by publishing a detailed list of the industrial accidents in 1907. According to this list there were 18,962 accident cases notified in Hungary during that year, showing an excess of 407 in comparison with the previous year. Out of all accidents only 1170 befell women owing to the comparatively small number of working women in Hungary and to the fact that those occupied with work are mostly employed at home. While out of 1000 male workers 39 suffered from accidents, out of 1000 female workers only 17 were in the like case. More than four-fifths of the injuries caused incapacity to work, lasting less than four weeks. Persistent partial incapacity was caused by 257 accidents. Persistent entire incapacity occurred in 19 cases. Fatal accidents were 225 in number. In more than four-fifths of the accident cases the limbs were injured. In factory work there were ten times as many accidents as in small industries. The working days lost by the accidents amounted to something over 300,000.

A School for Mothers.

To teach mothers how to preserve their children from infective diseases and how to nurse them when healthy or ill a school was opened in Budapest last year and has had an immense success. Every lecture (delivered by voluntary lecturers) was attended by audiences consisting of from 1200 to 1300 mothers. The first lecture was delivered this year in the town-hall by Dr. F. Torday, chief physician of the State Foundling Home. The title of his lecture was: "The Preservation of the Health of the Future Generation; the Prevention of Tuberculosis and Scrofulosis." The entrance to these lectures is free and men are not admitted. The order of the lectures is as follows: Dr. Presich lectures on Rickets; Dr. Wein on the Bodily Education of Children at Home; Dr. Deloe on the Essentials of the Infective Diseases and their Prophylaxis; Dr. Berend on the Nutrition of Infants; and Dr. Schaffer on the Mental Training of Children. The good effect of this school is shown by the following declaration of the wife of a State official. "The frequenting of the lectures of the 'School for Mothers' is exceedingly useful for us. We learn there different things, amongst them one thing particularly—in case of emergency not to cry and rub our hands but to send for the doctor immediately, and then such disaster as I was unfortunate enough to survive will be avoided. About two years ago my baby (aged one year) was attacked by cramps. His face became bluish and the eyes turned upwards. The instruction of the grandmother was of no use; the child did not regain consciousness. The blue tint of the face changed to mortal paleness; the baby's glassy eyes showed that he was dead. We began to cry bitterly; baby was really dead. Later I learned that a medical man might have saved him by applying artificial respiration. Such a mishap will never occur in a family where the mother has gained such useful information as we gathered in the School for Mothers."

Medical Men's Hours of Consultation.

Dr. Lenard advises his *confrères* in the *Orvosok Lapja* to quit the old custom of remaining at home to receive patients in the afternoon. This, he says, has many disadvantages for medical men. First and foremost the practitioner is occupied thus during the whole day. He sees his patients at that time (forenoon) when patients generally are at their easiest. The temperature is highest in the afternoon and lowest in the morning hours. By keeping office hours between 8 and 10 A.M. he can execute all the calls which arrive during this time. Then making the out-door visits till 2 P.M. (remembering that the severer cases should be left till after 12 noon) he sees his patients at the time when their temperature is rising. After 2 P.M. he is free and can no day nurse has keys, &c. If this be so important and so satisfactory a factor, why should it be limited to the day-time? But doubtless this point must be considered with the recovery-rate, which, be it noted, is at Woodilee, according to published statistics, about the lowest in Great Britain.

I trust this is due to the large number of cases of dementia admitted, which should also explain the absence of keys, &c.; surely it cannot be due to the elaborate intermingling of corrugated iron, "compo" boarding, open air, and female nurses. I do not throw doubt for a moment upon Dr. Marr's great ability, nor the entirely excellent organisation and administration of the asylum over which he so zealously presides; this, however, has nothing to do with the subject at issue. I am, Sir, yours faithfully,

MEDICAL SUPERINTENDENT,
County Asylum (England).

Feb. 6th, 1908.

ANÆSTHESIA AND ITS MORTALITY.

To the Editor of THE LANCET.

SIR,—A discussion on "deaths under chloroform" at the Medico-Legal Society is reported in the lay press. Dr. F. W. Hewitt is there stated to have recommended a higher system of tuition as to the administration of anæsthetics. It would be interesting further to strengthen such a recommendation, by an inquiry as to why, at provincial, Scotch, and Irish hospitals, the percentage of deaths connected with the administration of anæsthetics is so small as compared with the London statistics. I am told that at Edinburgh the specially instructed students often administer the anæsthetic, and, in chloroform anæsthesia, only use a towel. So I am told. Is the special instruction there more thorough than here? Dr. Hewitt generally has good reason for his opinions. I am, Sir, yours faithfully,

Feb. 12th, 1908. G. H. R. D.

THE SITE OF A SANATORIUM.

To the Editor of THE LANCET.

SIR,—As I am interested in the efforts of the medical profession to minimise the ravages of consumption, perhaps you will give me a few particulars as to the nature of the soil on which a sanatorium should be built. The Cork Conjoint Hospital Board has been offered, as a free gift, land on which to erect a public sanatorium. The proposed site has been described as a bog over which snipe have been shot; bulrushes grow on it; the surface-earth to the depth of 6 or 12 inches is peat mould, under which is a deep stratum of yellow clay; there are several small ponds or holes, from 8 to 12 feet in diameter, containing stagnant water; and in other places surface water lies on the ground. Would this be a suitable or unsuitable site? Would it be a good or particularly good site, a bad or particularly bad site? As I know your journal focusses medical opinion on such subjects perhaps you will excuse me for venturing to address you.

I am, Sir, yours faithfully,

Feb. 13th, 1908. VALETUDINARIAN.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—A great many opinions are finding expression as to how the work of medical inspection of school children shall be carried out, and it seems doubtful whether the uncertainty at this moment exhibited can be in any degree edifying to the powers that be, or to the public who are acting the part of lookers-on.

The last memorandum of the Board of Education issued upon the subject states that the difficulties to be encountered are chiefly administrative. Precisely so, but the Board of Education do not do much to diminish these difficulties. The few suggestions which they have made in this behalf are sufficiently confusing. That they are desirous of linking up this public health work with the other public health work is evident and that the medical officer of health, who is the chief public health officer, must take a prominent part in the business is equally manifest, but having given a hint of their desire in this direction, they have left it to the local education committees to make all appointments, and these committees are to do the work as well as they can, or as badly as they will. The Board of Education have said in their memorandum that the sanitary authorities should instruct their medical officers of health to go in and advise the education committees. This is rather cool of the Board of Education, who have nothing to do with the sanitary authorities or their medical officers of health. And here lies difficulty No. 1—that is, the complication of having the public health work of the country managed by two different sets of committees, the public health committees proper and the education committees. Unless a free hand be allowed the superintending officer to conduct the work without interference from the education committee, whose members are likely to think themselves quite capable of "directing" the work of medical inspection, the result must be confusion worse confounded. There is no direction in the memorandum of the Board of Education as to how these committees are to treat and pay their medical officers, but we know that these officers will be expected to subscribe to the farce that it is the committee and not the officer that does the work and is the responsible party. And what is the Local Government Board doing that they allow officers that erstwhile were under their own sovereign control to become the fags of a peregrine department?

As to difficulty No 2, the Board of Education's memorandum alludes to the medical officer of health as if the office of that person were perfectly satisfactorily established and as if the public health department of every town of 20,000 inhabitants, and of every county in the land, were efficient, whereas we know it to be far otherwise. We know that three parts of the public health service that is being called upon to undertake this tremendous accession of work is hopelessly inefficient and incapable of its performance. And yet this work cannot be divorced from the public health office; it is public health work. The medical examination of the children, which must be itself deputed to the general practitioner, must nevertheless be directed and supervised from the public health department, and this general direction is only a part of the work that will fall to the public health officer, for much more will ensue *as the result of* the examinations and in connexion with them. Yet with the public health service in the condition it is, what a putting of the cart before the horse is this business. Would it not be better for Parliament in the present session to pass a repealing Act, or the Board of Education to send round a notice postponing all action until we have the needed reform in the public health service?

The various and bewildered propositions as to the way the medical inspection of school children shall be carried out which are emanating from the education committees *as the* result of deliberations guided by competent or incompetent medical officers of health, or unguided altogether by any medical officer, only further serve to exemplify the ridiculous condition of our public health administration, and of the absurdity of supposing that a work of such special character and national effect as that in question can be accomplished nationally by the independent ungoverned action of hundreds of different committees, or, for that matter, by as many medical officers of health acting without any general governance, constraint, or co-relation.

I am, Sir, yours faithfully,

Feb. 17th, 1908. M.D., D.P.H., M.O.H.

THE UNIVERSITY OF LONDON AND PROVINCIAL STUDENTS.

To the Editor of THE LANCET.

SIR,—May I, in the name of the numerous external students of the University of London, protest against the absurd length of time they are made to stay in town when *sitting for the final M.B.* examination? If a candidate takes all the subjects at one time he is kept up for three weeks. He has a good deal of his time wasted and in many instances his concluding tests are given to him *after* students residing in London have received theirs. In the case of a candidate only taking half the examination at a time the evil is much worse, for there is then an interval of eight or nine days of idleness provided for him. He has either to remain in London at considerable expense, or make two or more journeys to the provinces, which may be equally expensive. I consider that the authorities can, if they choose, remedy this state of affairs. I am, Sir, yours faithfully,

Feb. 18th, 1908. PROVINCIAL.

Obituary.

SIR JOHN DENIS MACDONALD, K.C.B., M.D. ST. AND., M.R.C.S. ENG., F.R.S.,

INSPECTOR-GENERAL R.N. (RETIRED).

ON Feb. 7th there passed away at Southsea, full of years and honour, one of that distinguished band of men of science who notably advanced the study of biology during the middle of the last century by its eager pursuit in deep waters. Sir John Denis Macdonald's services to science gained him the Fellowship of the Royal Society and his services to the navy won him a Knight Commandership of the Bath of the military division. He was born in 1826 and was the son of Mr. James Macdonald, an artist of Cork, a parentage which in some measure shaped his own subsequent tastes. He was educated privately and subsequently entered the Cork School of Medicine; his medical career, however, owed something to all three divisions of the British Isles, for he studied at King's College, London, and derived his M.D. in 1867 from St. Andrews. He qualified M.R.C.S. Eng. 18 years earlier and in the same year (1849) entered the Royal Navy as an assistant surgeon. His scientific tastes and faculty for classification at once gained him the post of curator to the Plymouth Hospital Museum and his bent also lay to the personal cultivation of the fine arts, a combination of tastes in a man of science as welcome as it is rare. Three years later H.M.S. *Herald* was commissioned for exploring and surveying work in the South Pacific, and Macdonald was gazetted to assist in the second of the great British marine explorations of the last century, 20 years later than Darwin had made his historical voyage in the *Beagle* and 20 years before Wyville Thomson won another laurel for British science in the *Challenger*. It may fairly be said that Macdonald's work ranks with that of those men and he pursued it unremittingly for seven years, bringing within the focus of his microscope many thousands of forms of marine life which had been netted and dredged. The value of his work was recognised in England and when he returned in 1859, at the early age of 33, he was made a Fellow of the Royal Society. In 1862 the sister society of Edinburgh awarded him the Macdougall-Brisbane medal, and gaining steady promotion in his service he was elected professor of naval hygiene at the Netley School in 1866, a post which he held for nine years. In 1871 he obtained further distinction in the shape of the Sir Gilbert Blane medal. His next promotion was in 1875, when he became a deputy inspector-general of hospitals and fleets, and in 1883 inspector-general to the Royal Naval Hospital at Stonehouse. He only held this post for three years, as he retired from the service in 1886. His knighthood was conferred upon him in 1902, and he has since lived in retirement.

Macdonald's contributions to literature included "An Analogy of Sound and Colour," published in 1869; "Outlines of Naval Hygiene" in 1881; "A Guide to the Microscopical Examination of Drinking Water" in 1883; the article on Yellow Fever in the first volume of Reynolds's System of Medicine in 1866; and various papers on biological matters in the Transactions of the Royal Societies of London and Edinburgh and of the Linnæan Society. He maintained his interest in microscopy, music, and painting until the last. He was a man of distinguished appearance and fine culture and his death has removed another of the few remaining leaders of science of the nineteenth century.

Sir John Macdonald was twice married, first in 1863 to Sarah Phœbe, daughter of Mr. Ely Walker, of Stanary House, Stainland, Yorks; this lady died in 1885; and secondly to Erina, daughter of the Rev. William Archer, who also predeceased him. He leaves two sons and two daughters and had resided with one of the latter, who is married to Mr. W. R. Meyer of Hurstpierpoint in Sussex, for the last ten years.

JOHN HENRY GALTON, M.D. LOND., M.R.C.S. ENG., L.S.A.

WE regret to announce the death of Dr. John Henry Galton, which took place at his residence, Chunam, Upper Norwood, on Feb. 7th. He was well known to several branches of the profession as a man who had always laboured to support its best interests; indeed, his fatal illness was directly due to his unwisely attending a meeting of the Council of the British Medical Association some ten days before he died, which was the occasion of his taking a chill resulting in a fatal bronchitis. For the last two years his heart and kidneys had shown signs of failing and last summer, after a visit to Aix-les-Bains, he broke down badly, but with rest and careful treatment he was able to be about again, though not enough to satisfy a man of his active disposition. Dr. Galton was the son of Dr. Edmund John Galton of Brixton Rise and was born in 1840; he was educated at Chatham House School, Ramsgate, and entered Guy's Hospital before he was 16 years old. He had a successful career as a student and in 1861 he obtained the qualifications of L.S.A. and M.R.C.S. Eng., and in the same year the degree of M.B. at the University of London, with the gold medal in midwifery, his M.D. following a year later. He served as house surgeon at his own hospital and then became resident medical officer at the Carey-street Dispensary. After these close years of London life he was attracted by the prospect of travel and obtained the surgeoncy of the Hudson Bay Company's vessel the *Prince Arthur*. He only made one voyage in her, however, and then turned his steps to the East, settling down in China, at Foochow, where he obtained the official medical appointments to H.B.M. Consulate, the gaol, and H.I.M. Customs. These posts gave him an opportunity of acquiring a wide practical knowledge especially of surgery, to which he had been early attracted. He operated freely on cases of elephantiasis. He was not to spend his days in a foreign land, for in five years he decided to return to England, and shortly after he had done so he married and settled down at Anerley in partnership with Mr. J. Sidney Turner, a partnership which was only terminated at the end of last year. He became one of the leaders of the medical profession in his district and in 1882 was largely interested in helping to found the Norwood Cottage Hospital, of which he was one of the original honorary surgeons, and to which he was appointed consulting surgeon on his retirement when his health first began to give way. He was also surgeon to the Anerley Dispensary and Lying-in Charity and his interest in gynæcology is evidenced by several contributions which he made to our columns between 1884 and 1887 dealing with cases of Cæsarean section and ovariotomy. It has been mentioned that he was at the time of his death a member of the council of the British Medical Association, of which he was a prominent supporter, having held the post of President of its South-Eastern Branch. He was the originator of the movement in favour of admitting medical women to the Association, and the successful issue of that movement was largely due to his powerful advocacy. Another valuable medical institution to which he gave his whole-hearted labour and support was Epsom College, with which his official connexion began in 1885, when he was elected a member of the council, and his interest in its affairs has been actively maintained. Until within the past few months, when continued ill-health prevented him from attending at the office in Soho-square, he rarely failed to be present at council and committee meetings and he was specially devoted to the benevolent side of the institution. Many a widow and orphan will miss his kindly interest in their cases, for he took a genuine interest in assisting by his votes those candidates whom he knew personally to be deserving of support, especially when, as sometimes was the case, they were the relatives of an old professional friend. In 1902 he was elected a vice-president of the institution in recognition of his having collected a sum of over £1000 in aid of the foundation attached to the college, and subsequently he was elected chairman of the finance and works committee, which offices he had to resign within two years in consequence of persistent ill-health. Whilst chairman of the works committee he took a leading part in the work of bringing the drainage system and the sanitary arrangements at the college to their present excellent condition at a total cost of £8000 and he paid frequent visits to the college as long as he was able to travel about. He originated the idea of providing the boys with the "Holman" art and reading room, which was erected out of contributions collected entirely by himself, to commemorate the services rendered to the college by his old friend Sir Constantine Holman, M.D., who then held the office of treasurer. These two were also closely associated in the work of the Surrey Medical Benevolent Society for very many years, Sir Constantine Holman holding the office of president and Dr. Galton the office of treasurer. His death cannot but be felt keenly by all who are the "slink butchers" show. Even Sir James Crichton-Browne comes under animadversion as exaggerating the defects of *private slaughter-houses, and the President boldly challenged* a comparison between them and the public slaughter-houses. Another argument was that if these private slaughter-houses were abolished "it would be one of the greatest blows agriculture had ever received," and very few would say in these days that our agriculture required any more blows. There was a strong feeling that as to the sale of meat which was diseased the butchers had just cause of complaint. For years the Federation had been fighting for compensation where tuberculous meat had been surrendered to the authorities for the public good. At present they are liable to penalties, and the relief they want is a warranty between the seller of the livestock and the meat-trader, "a full warranty throughout the United Kingdom." There will occasionally, no doubt, be cases of hardship where beasts sold to the butcher as healthy are found on his stall diseased; but as a rule he is acute enough to distinguish a diseased or doubtful beast. The system of inspection is *objected to*, as the butcher is not allowed to have an "independent expert" on his side. All these things and a few others no doubt take some of the glamour from the trade of butchering, but the health of the people is the paramount consideration.

Annual Meeting of the Trustees of the Royal Infirmary.

At the annual meeting of the trustees of the Royal Infirmary on Feb. 14th Mr. Cobbitt, the chairman, said that they had every reason to expect that the building would be completed by July 31st; and there was an urgent need for the subscriptions of the general public to be increased. He used an ingenious argument to show that the "district served by the infirmary could well afford to maintain it at the high level necessary, especially considering that following the trade boom of the past few years there should now be accumulated profits at the disposal of the community." Mr. Nevill Clegg, vice-chairman, followed up this appeal by saying that, apart from trade fluctuation, there was wealth enough in the district "to raise twice the sum of £7000 which was now contributed." No doubt this is so, and very little sacrifice on the part of "the general public" would be required to put the infirmary into a sound and satisfactory financial position. At present those who have worked for it so long and strenuously cannot but feel anxious for the future, faced as they are with the certainty of largely increased expenditure and, it is to be feared, a diminished feeling of duty or inclination to give to old-established medical charities.

Early Notification of Births.

The Medical Guild has expressed its strong objection to the Early Notification of Births Act in a letter from Dr. J. H. Taylor (the honorary secretary) to the Manchester papers. One objection is the disregard shown to what the medical profession holds as one of its most sacred duties—namely, "that it shall not divulge any facts learned in a professional capacity." Also that "it so utterly scorns the rights of medical practitioners that they have been completely alienated." Dr. Taylor says it becomes more and more evident that the Act has little chance of proving a success in its present form, and that "it is to the credit of the Manchester council that it has recognised this fact." At the annual meeting of the Guild the following motion was carried:—

> That the Medical Guild notes with great pleasure the refusal of the Manchester city council to adopt the Early Notification of Births Act, but, recognising the advantage to be gained in many cases by early assistance being given to nursing mothers by the health authorities, would urge its members and the medical profession generally to facilitate matters to the best of their ability by advising their patients in suitable cases to give early notification of births and to make application for any required assistance to the health department.

Mrs. Ryland's Will.

The provisions of Mrs. Ryland's will have been so widely quoted in the lay press that detailed mention of them here is unnecessary. The bequests to medical charity are substantial, and although the exclusion of the Royal Infirmary from benefit cannot fail to provoke comment the generosity displayed towards the Manchester Eye Hospital, the Dental Hospital, and the Hospital for Incurables is great. Medical men in Manchester also feel that they will have an intimate share in the good that will follow upon the bequest of £50,000 to the University. The largest legacy in the will, £200,000, was left for the up-keep of the John Ryland's Library, Mrs. Ryland's splendid gift to the city.

Feb. 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Local Government Board in Scotland.

THE Commission recently appointed by the Local Government Board for Scotland to inquire into complaints made concerning the fever hospitals at Falkirk and Ruchill has led to comment that may be useful upon this important Government department. The *Glasgow Herald*, in commenting on the relation of the Local Government Board to the various hospitals for infectious diseases throughout the country, points out, what must be manifest to medical men, that while it is the duty of the Board to inspect hospitals *for infectious* diseases and to compel local authorities to remove any existing defects the Board does not possess a staff adequate in numbers to undertake such work. The Local Government Board in England has one medical officer who is head of the medical department, one assistant medical *officer*, and 14 *medical inspectors* proper, besides two medical inspectors for Poor-law purposes. Ireland has one medical member on the Board and seven medical inspectors. The Local Government Board for Scotland, like the Irish Board, has one medical member but only one medical inspector and one part-time medical officer. Leaving England *out of the question*, it would appear that although Ireland and Scotland have roughly the same population the former has seven medical inspectors to the latter's one. It has been urged that there should be a regular inspection of infectious hospitals but one medical inspector is quite unfit to undertake a continuous round of such *systematic duties* as he ought to be engaged in. In Scotland, also, there are 69 poorhouses which must contain in the aggregate a very large number of sick people but the inspection of these is entirely left in lay hands. There is surely some room for improvement here.

Turner Memorial Hospital, Keith.

The annual meeting of the directors of the above hospital was held in the institution in the end of January. A report was read showing that after careful consideration the committee had come to the conclusion that the best use to which the improved finances of the hospital could be put was to make provision for the relief of patients suffering from consumption. A scheme was then approved for the erection of a sleeping shelter in the hospital grounds for the accommodation of two patients, the estimated cost for construction being about £60. In the course of the year 67 patients have been treated in the hospital and of these 43 have recovered, seven improved, eight have died, and nine remained in hospital on *Dec.* 31st last. The financial report for the year was satisfactory.

The Queen and Glasgow Maternity Hospital.

The Secretary for Scotland has intimated that Her Majesty the Queen has been graciously pleased to accept the office of President of Glasgow Maternity Hospital. It is expected that the new hospital will be opened in April.

St. Mungo's College, Glasgow.

The Lord Provost of Glasgow, Sir William Bilsland, who also occupies the position of chairman of the managers of the Royal Infirmary, visited Liverpool last week in connexion with the question which has arisen as to the future of St. Mungo's College and its relation to the Royal Infirmary. In Liverpool similar difficulties arose regarding medical teaching and were amicably arranged, and it is hoped that the Lord Provost, after consultation with the Lord Mayor of Liverpool, who is a prominent medical man, may be able to suggest a scheme that will prove satisfactory to all parties.

Cancer Research Appointment.

Dr. Archibald Leitch, of the Cancer Research Laboratories, the Middlesex Hospital, London, has been appointed investigator at the Caird Cancer Pavilion of the Dundee Royal Infirmary. Dr. Leitch is a graduate of the University of Glasgow and during the last five years has been engaged in cancer investigation at the Cancer Hospital, London, and later at the Middlesex Hospital Cancer Research Laboratory. He is the author of several papers on the subject, and recently was sent to Paris to inquire into and report on particular methods of treatment there. The new appointment is made under a grant of £1000 a year for five years by Mr. J. K. Caird, Dundee, for cancer research.

Aberdeen Royal Infirmary: Annual Report.

The twenty-first annual report by the directors of the

Medicine for Women; Cecil George Richardson, King's College and Westminster Hospital; Edward Hesketh Roberts, University College; Arthur Denys Rope, Middlesex Hospital; David Scurlock, St. Mary's Hospital; Edward Albert Seymour, St. Thomas's Hospital; Robert Stout and ‡Graham Yaldon Thomson, Guy's Hospital; Marjorie Edith Wagstaff, London (Royal Free Hospital) School of Medicine for Women; Ernest White, St. Bartholomew's Hospital; ‡William Stanley Wildman, London Hospital; and Charles Witts, Guy's Hospital.

The following candidate having qualified in organic chemistry has now completed the Intermediate Examination in Medicine:—

Phirozshaw Cooverji Bharucha, University College.

* Distinguished in Anatomy. † Distinguished in Physiology.
‡ Distinguished in Pharmacology.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

UNIVERSITY OF OXFORD.—The following have been re-elected members of the Board of the Faculty of Medicine: J. R. Magrath, D.D., Provost of Queen's College; F. A. Dixey, D.M., Fellow of Wadham College; A. L. Ormerod, D.M., New College; W. Bruce Clarke, B.M., Pembroke College; and A. P. Parker, B.M., Magdalen College.

THE TREATMENT OF STAMMERING AT ELEMENTARY SCHOOLS.—In our issues of Oct. 19th and Nov. 16th, 1907, we commented on the success which had been obtained in the treatment of stammering in children attending elementary schools, the instructors being Mr. W. A. Yearsley in Darwen and Miss Mona Clay and Professor Berquand in Manchester. Mr. Yearsley employs what he calls the "auto-phonic" system; it commences with "breathing exercises," after which come vocal gymnastics, and then a combination of vocal, breathing, and physical exercises, together with dumb-bell practice. The course of instruction lasts for about six weeks. The system has received the approval of the education authority in Radcliffe, Lancashire, where a class was formed of 23 boys and nine girls, all of whom suffered from stammering, stuttering, or defective articulation. Dr. D. P. M. Farquharson, the medical officer of health of Radcliffe, in a report presented to the education authority, gave a very favourable account of the results, and eight weeks after the termination of the instruction the education committee on putting the children to practical tests found that the improvement was well maintained.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN SUSSEX.—The West Sussex county council had before it at its meeting on Feb. 7th the application of the West Sussex education committee for the appointment of a county medical officer for the purpose of working and supervising and, as far as possible, performing the duties required by the Act. The finance committee of the county council recommended that the education committee should be empowered to proceed with its proposals upon the estimate submitted—viz., £675 per annum. Considerable objection was raised, it being considered inexpedient for the education committee to appoint a medical officer, as it was considered that those duties could, and should, be carried out in intimate conjunction with the public health authorities under the direct supervision of their own medical officers of health. Another objection was that there were enough inspectors going about already and that if the education committee appointed a man he would be a specialist, "and specialists are always men of narrow minds," to use the councillor's own words. But beyond being emphasised the various objections were not put to the vote, and in the result the committee's recommendation was carried. At a subsequent meeting of the education committee, however, it was announced that Mr. E. I. Bostock of Horsham, who has recently retired from practice, had offered to carry out, without remuneration, the duties until the committee had made further arrangements. This offer was accepted as an experiment, the chairman remarking that, of course, the committee would give Mr. Bostock an honorarium.—Acting upon the advice of Dr. A. Newsholme, the late medical officer of health of the borough, the Brighton town council on Feb. 6th decided to appoint a whole-time medical officer to carry out the medical inspection of schools under Section 13 of the Education (Administrative Provisions) Act, 1907. There are 18,000 children in the elementary schools of the town, and the council, reckoning that of this number 6000 will require to be inspected medically annually, decided that the salary should be at the rate of one shilling per head per inspection, or £300 per annum. At the same meeting it was decided to appoint an additional school nurse at a salary of £90 or £100 per annum.

CHELSEA CLINICAL SOCIETY.—The annual dinner of this society will take place at the New Gaiety Restaurant, Strand, on Thursday, Feb. 27th, at 7.45 P.M. All information concerning dinner tickets and tickets for guests can be obtained from Dr. K. R. Collis Hallowes, 104, Buckingham Palace-road, London, S.W.

CLIFTON DISPENSARY.—The annual meeting of the subscribers to this institution was held on Feb. 4th. The medical report stated that during 1907 there were 3149 patients treated (including 67 cases of midwifery), as compared with 3612 in the previous year. The financial statement showed a small unfavourable balance.

BRISTOL EYE HOSPITAL.—The annual meeting of the subscribers to this hospital was held on Feb. 5th under the presidency of the Lord Mayor. The annual report stated that during 1907 the in-patients numbered 513, being 59 in excess of the previous year; and that 7397 out-patients had been treated as compared with 6805 in 1906. The financial statement showed an unfavourable balance of £537.

METROPOLITAN ASYLUMS BOARD.—This Board at a recent meeting decided to increase the remuneration of medical superintendents in the hospitals as follows: Salary (1) commencing at £500 per annum and rising by four annual increments of £25 to £600 per annum, and thence by two further annual increments of £50 to £700 per annum; and (2) after the expiration of ten completed years of service as a medical superintendent to rise from £700 per annum by £50 annually to a maximum of £800 per annum. The emoluments consist of unfurnished house (or furnished apartments) and washing. The salary hitherto assigned to a medical superintendent commenced at £400 and rose annually by £25 to a maximum of £700 per annum with emoluments of unfurnished house (or furnished apartments), washing, fire, and lighting.

UNIVERSITY OF SHEFFIELD.—The Council of the University has appointed Mr. John L. Annan, M.B., Ch.B. Edin., to the post of Demonstrator in Anatomy. Dr. Annan is at present Demonstrator of Anatomy in the University of Edinburgh and house physician in the skin wards of the Edinburgh Royal Infirmary. The Council has also appointed the following gentlemen to the newly instituted clinical tutorships: Mr. Miles H. Phillips, M.B., B.S. Lond., F.R.C.S. Eng., in Obstetrics and Gynæcology; Mr. Graham S. Simpson, F.R.C.S. Eng., in Surgery; and Mr. A. E. Barnes, M.B. Lond., M.R.C.P. Lond., in Medicine. Dr. Phillips is the assistant medical officer at the Jessop Hospital for Women and Mr. Simpson is the assistant surgeon at the Sheffield Royal Hospital. Dr. Barnes holds a British Medical Association Research Scholarship and is at present engaged in research in the Pathological Laboratory of the University.

THE ANNIVERSARY DINNER OF THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The twenty-sixth anniversary dinner of this society was held under the chairmanship of Mr. Richard Lake, the President, on Feb. 13th at the Wharncliffe Rooms, Hotel Great Central, Marylebone, London, and the occasion proved a great success, for which due praise was accorded to Dr. F. G. Crookshank, the senior secretary, and his colleague, Mr. A. Baldwin. "The Imperial Forces" was proposed by Mr. Herbert W. Chambers and was responded to by Colonel A. T. Sloggett, R.A.M.C. The chairman submitted the toast of the evening, "The West London Medico-Chirurgical Society." He was able to report that the finances were in a healthy condition and that the ordinary meetings of the society, of which nine were held during the session, had been well attended, the average number present at each meeting being 41. He was happy to state that there was an increase in the total membership, the number of members nearly reaching the total of 700. More books were being added to the library and there was a satisfactory arrangement for supplying members with an opportunity of seeing newly-published works. He concluded his speech with a graceful reference to the founder of the society, Mr. C. R. B. Keetley. Dr. A. J. R. Oxley proposed the toast of "The Kindred Societies and Guests," in the course of which he referred to the services rendered to the profession by Sir William S. Church, President of the Royal Society of Medicine. Sir patient going to the medical man or *vice versâ*, it could be given by the mouth in the ordinary manner.

Obituary.

Dr. Peyron, formerly Director of the Assistance Publique and also of the department which dealt with deaf mutes, died last week. He was Director of the Assistance for 14 years, but latterly had retired to Marines in the department of Seine-et-Oise.

Feb. 18th.

COPENHAGEN.

(FROM OUR OWN CORRESPONDENT.)

The Bacteriological Examination of Sputum and Urine.

ALL pathologists know how difficult it often is to find tubercle bacilli in specimens where only a few are present, and those perhaps not uniformly distributed throughout the substance under examination. Researches made by Dr. Ellermann and Dr. Erlandsen and communicated by them to the last meeting of the Copenhagen Medical Society have led to the adoption of a new method which increases the relative number of the bacilli from 10 to 20 times. Sputum is treated as follows: (1) 20 cubic centimetres of sputum are carefully mixed with 10 cubic centimetres of a 0·6 per cent. solution of carbonate of sodium and placed in the thermostat (37° C.) for 24 hours; (2) the sputum is centrifugalised; (3) four parts of a 0·25 per cent. solution of caustic soda are added to the deposit, mixed carefully, and boiled for half a minute; and (4) it is again centrifugalised. Urine is treated somewhat differently to begin with. First, the clear urine is poured off the sediment, which is subsequently centrifugalised. To the resulting sediment four parts of a 0·25 per cent. solution of carbonate of sodium are added with from 25 to 50 centigrammes of pancreatin; it is placed in the thermostat (37°) for 24 hours, and subsequently treated as sputum in directions (3) and (4) above.

A Boycott of the Copenhagen Hospitals.

Danish medical circles have been much interested in the struggle that has arisen between the municipality of Copenhagen and the Association of Junior Medical Men. In order to explain to an English public the object of the conflict and its importance I must in a few words deal with the way in which hospitals are managed in Denmark, as on this point a great difference obtains from what is customary in England. In the first place, hospitals supported by private subscriptions are here practically unknown save some few minor institutions maintained by Roman Catholic religious orders. The Crown supports one (University) hospital with 300 beds, which takes in such patients from the whole country as are considered suitable for the instruction of the medical students. All other hospitals are managed by the different municipalities themselves, the expenses being chiefly defrayed out of the rates. Only a comparatively small amount is paid by the patients or by the sick clubs of which they are members. For a town like Copenhagen this expense forms, of course, rather a heavy item. The municipality of Copenhagen has 430,000 inhabitants and supports ten hospitals with a total of 2900 beds, besides a lunatic asylum of 1400 beds. The total yearly outlay on the hospitals alone (the lunatic asylum not included) is somewhat below £200,000. Of this sum £150,000 a year are paid directly from the rates, the rest being paid by the patients, the clubs, the Crown, and so forth. The other point in which our hospital management differs from English ways is this, that our hospital staffs are not composed of honorary medical officers. Not only are the resident medical officers paid but so also are all the medical men who visit the hospitals. Of course, the salary is highly inadequate, and the Association of Junior Medical Men, which numbers amongst its members all Danish medical men not yet in actual practice as well as all junior medical officers of the hospital staffs, has therefore considered it highly important to try to obtain an improvement in the salaries. A year ago one party of the town council of Copenhagen had at last granted the very modest wishes of the association, but at the final discussion in the council one of the members—I am sorry to say it was a colleague of ours—saw fit to oppose the proposal, which was therefore only passed a few days ago and in a badly modified form. The Association of Junior Medical Men at once resolved to act on the offensive and with the support of the Danish General Medical Association, which latter numbers amongst its members practically all medical men in practice, it has now invited all medical men in Denmark to abstain from applying for appointments in the Copenhagen municipal hospitals. As the profession in Denmark forms one compact body, outsiders being very scarce, and as a great number of appointments in the said hospitals will shortly become vacant, the pressure brought to act on the town council is very strong. In order to insure the proper care of the sick during the struggle the association is offering the municipality to procure any requisite number of locum-tenents, but of course their salary would be the ordinary rather high one paid by the medical men themselves. This boycott certainly smacks of trade unionism, but the time has finally come for the profession to see clearly that this is the only way in which it can maintain its position. It is confidently expected that this struggle will end in a victory for the profession. The outcome of the struggle is all the more important in that very soon the whole medical system of Denmark is to be discussed and altered by a Royal Commission. Other important questions are also pending—e.g., that of the salary of sick club medical officers. If the profession wins in the present struggle the result cannot fail to influence the solution of the other questions in a way favourable to ourselves.

An Interesting Method of Raising Funds for Benevolent Institutions.

Signs are not wanting to show that the Danish National League for Combating Tuberculosis is now nearing it sgoal as far as the establishment of a sufficient number of sanatoriums for the poorer classes of the population is concerned. But while this has been brought about by the work and contributions of a comparatively restricted number of persons throughout the country, the promoters of a scheme for a special children's sanatorium have succeeded in interesting all classes of the community, rich and poor alike, in their object and that in a practical manner. This has been attained by the issue of a special Christmas stamp which for the four last years has been sold at all post-offices (price one farthing) from a little before Christmas until New Year's Eve. Any letter posted in Denmark during that space of time carries besides the ordinary postage one or more of the Christmas stamps. The whole output of the sale of Christmas stamps goes towards the children's sanatorium; it has during the four years reached a total of £20,000, certainly a very good result considering the fact that Denmark only has 2,500,000 inhabitants. This plan might perhaps be adopted by other and greater countries for raising funds for benevolent institutions. The Crown suffers no loss from the scheme as the usual postage has to be paid in ordinary stamps.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Special Charges for Dispensing Medicines at Night.

BY an understanding arrived at recently between all the corporations concerned the Society of Apothecaries has given public notice that in future for all prescriptions, with one exception, an extra charge of about 6*d*. will be made if they are dispensed at night time—i.e., after 9 P.M. and before 7 A.M. This extra 6*d*. will be handed over to the fund for the old-age pensions of the apothecaries' assistants. If, however, the medical man adds the letters "E. N." (*expeditio nocturna*) to the prescription it will be free from the extra charge and this is expected in all urgent night cases. As a good many prescriptions and pharmaceutical preparations have been obtained by the public after the usual business hours, and as only the regularly constituted apothecaries are, in this country, allowed to make up prescriptions the abuse has grown very much during the last few years. The raising of the charges for dispensing is not without interest for the medical profession because those village practitioners who have dispensaries of their own attached to their consulting-rooms will also be obliged to charge the increased sum for dispensing at night.

Death of Professor Frühwald.

Professor Frühwald, one of the best known Vienna specialists for children's diseases, died recently. He was a pupil of Professor Widerhofer, from whom he learned the

16. In the case of "other tobacco" mere possession does not constitute the proposed offence. It must be destined for the use of the juvenile delinquent. Exemption to young persons employed in the tobacco trade is given, in so far that they may continue their employment, but they are prohibited from smoking in the same way as if they were not employed in the business. A clause of the Bill deals with automatic machines for the sale of tobacco or cigarettes. It is proposed to endow courts of summary jurisdiction with powers to order the person on whose premises such a machine is kept to prevent it being extensively used by children and young persons for obtaining tobacco. Non-compliance with this order renders the person against whom it is made liable to a fine, which may be increased daily so long as his offence continues. However, he may either himself or by his agents make seizures of the cigarettes and tobacco obtained from the machine by young persons apparently under the age of 16.

The Children's Bill has been received with much satisfaction in all quarters of the House of Commons. Many of its provisions are generally conceded to be long overdue. In a measure of such length, however, there are almost bound to be clauses which in their drafting are unacceptable to some members. Mr. SAMUEL, who has been taking charge of the Bill, has approached the House in such a conciliatory spirit as to give the impression that the Government will exert itself to remove difficulties of this kind from the progress of the measure.

Infant Life Protection Committee.

The promised select committee of the House of Commons has been constituted to inquire into the advisability of extending the Infant Life Protection Act, 1897. The committee, which is a small one, has already set to work. Mr. JOHN ELLIS has been chosen as chairman. Steps have been taken to secure the attendance of witnesses competent to speak on the subject. The committee will meet again this week and it is understood that it will use the utmost despatch in completing the inquiry.

Poisons and Pharmacy Bill.

The Earl of CREWE has introduced into the House of Lords a Bill "to regulate the sale of certain poisonous substances, and to amend the Pharmacy Acts." The Bill was read a first time.

Nurses (Registration) Bill.

Mr. CLAUDE HAY has introduced into the House of Commons a Bill "to regulate the qualifications and registration of trained nurses." Sir ARTHUR BIGNOLD is associated with Mr. HAY in bringing in this Bill, which was read a first time.

Medical Practice by Companies.

Sir JOHN BATTY TUKE on Wednesday introduced into the House of Commons a Bill to prohibit joint-stock companies from acting as physicians, surgeons, or medical practitioners. The Bill as a matter of form was read a first time. Legislation dealing with this subject passed through the House of Lords last year, but owing to the congestion of business it failed to be considered by the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 12TH.

Deaths from Starvation in London.

Mr. SUMMERBELL asked the President of the Local Government Board what were the number of deaths in 1907 in London upon which a coroner's jury returned a verdict of death from starvation or death accelerated by privation; how many of these took place in Whitechapel; if he had not yet received the Home Office returns as to these deaths, whether he would without delay obtain from the Whitechapel guardians or from the Poor-law inspector of the district the number of such deaths from starvation in Whitechapel in 1907; and whether he had conferred, or would confer, with the guardians of Whitechapel as to steps to prevent or diminish the number of such deaths.—Mr. BURNS replied in a written answer: I am not able to give the numbers for the year 1907, as the necessary particulars have not yet been obtained by the Home Office from the coroners. I have communicated with the clerk to the Whitechapel guardians as to the occurrence in that union in 1907 of cases of the kind referred to, and I am informed that the medical superintendent of the infirmary has caused a search to be made and can find only one such case—namely, that of George Wright who died on July 25th last and in respect of whom the verdict of the coroner's jury was that he died from pneumonia accelerated by neglect and want of food. I will inquire as to the circumstances of this case, but I am not at present aware of any need for action of the kind suggested in the concluding part of the question. In connexion with this matter the character of the district and the large number of persons of migratory habits attracted thereto by free shelters and common lodging-houses must be borne in mind.

Overcrowding in Scotland.

Mr. DUNDAS WHITE asked the President of the Board of Trade whether his attention had been called to the fact that in the recent report on the cost of living of the working classes in the principal industrial towns of the United Kingdom, the percentages of the total populations occupying overcrowded tenements—i.e., more than two persons per room—were given for the specified towns of England, Ireland, and Wales, but not for the specified towns of Scotland, it being stated that the figures for the Scottish towns were not available; whether he could state what were the corresponding figures for those Scottish towns; and whether he would consider the advisability of framing the forms for the next Census so as to obtain that information.—Mr. SINCLAIR, the Secretary for Scotland, sent the following written reply:—My attention was directed some time ago to the fact that the figures referred to are not given in the Scottish Census Report, and under my instructions a return has been prepared for presentation to the House which will give full information on the subject for the whole of Scotland. The figures for the specified Scotch towns are as follows:—

Town.	Percentage of population living more than two in a room.
Aberdeen	38·1
Dundee	49·44
Edinburgh	32·94
Glasgow	54·7
Greenock	54·17
Kilmarnock	55·94
Leith	43·8
Paisley	58·76
Perth	28·26

My honourable friend will remember that the Board of Trade report draws attention to the fact that the tenement system of blocks of small flats is in Scotland the normal type of working-class dwelling, and that the rooms are generally much larger than those of an English cottage. The question of including these figures in the next Census Report will receive consideration.

THURSDAY, FEB. 13TH.

The Sale of Tuberculous Cattle in Scotland.

Mr. CATHCART WASON asked the Secretary for Scotland whether he was aware that in Scotland cattle in the last stages of tuberculosis were occasionally exposed for sale and food in the open market, with consequent risk of spread of the disease and danger to human life; and whether he proposed to take any steps by legislation or otherwise in order that persons submitting dying diseased cattle for sale might be prosecuted.—Mr. SINCLAIR replied: Section 43, 1 *a* of the Public Health (Scotland) Act, 1897, enables the officials of the local authority to seize animals that are intended for the food of man and are exposed for sale if they are diseased or unsound or unfit for the food of man, and the person to whom the animal belongs is liable to prosecution. The officials of the local authorities make use of this power and there does not seem need for fresh legislation in the direction suggested.

St. Andrew's Ambulance Classes.

Major ANSTRUTHER-GRAY asked the President of the Board of Trade whether instructions had been given to oblige Scotch candidates for master and mates first-aid certificates to qualify through St. Andrew's Ambulance instead of St. John's; whether he was aware that the yearly St. Andrew's course consisted of 144 lectures, while that of St. John's was only 52, and that the St. Andrew's Ambulance course was therefore more expensive in time and money than that of St. John's; whether the St. John's Ambulance classes, hitherto conducted on the East Coast of Scotland, had proved satisfactory; and, if so, why a system involving more time, trouble, and expense was enforced in Scotland and an easier system deemed sufficient for English candidates.—Mr. KEARLEY (Parliamentary Secretary to the Board of Trade) replied: Before granting a certificate for master or mate we require a man to have a knowledge of first-aid to the injured. This he can acquire through attending a course under either of the societies mentioned in the question. We have been in communication with the two societies, and as the St. John Ambulance Association informs us that it has centres at one or two Scottish ports only we have arranged with the St. Andrew's Society that courses should be available at all the chief ports in Scotland. If the suggestion in the question is that the Board imposes attendance at one society's course rather than the other the honourable and gallant Member is under a misapprehension.

Medical Inspection of School Children in Ireland.

Mr. JEREMIAH MACVEAGH asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the resolution of the Irish Committee of the British Medical Association, urging the necessity of the medical inspection of school children in Ireland on the lines already adopted by legislation with regard to England; and whether, having regard to the fact that every argument for such inspection in England applied with even greater force to Ireland, he would consider whether steps could be taken to give effect to this recommendation.—Mr. BIRRELL answered: I have received a communication from the Irish Committee of the British Medical Association to the effect stated in the question. I have been in communication with the Commissioners of National Education upon the subject generally and the matter is to be further considered by the Commissioners at their meeting next week. I would therefore ask the honourable Member to defer the question for the present.

FRIDAY, FEB. 14TH.

Diphtheria in Wood-Pigeons.

In answer to Major ANSTRUTHER-GRAY,

Sir EDWARD STRACHEY (representing the Board of Agriculture) stated that the Board was aware of the prevalence of the disease called diphtheria in wood-pigeons in several counties in England. That department understood that scientific investigations were being made, the results of which would be carefully watched. They did not think that the matter could with advantage be made the subject of inquiry by a commission. As to whether the disease was of a nature to be dangerous to man, he would bring the subject before the Local Government Board, by which questions concerning the public health fell to be considered.

MONDAY, FEB. 17TH.

Malta Fever.

Mr. MALLET asked the Secretary of State for War whether he was aware of the public service rendered by a commission of the Royal Society, at the request of the War Office and the Admiralty, in discovering the cause of Malta fever, from which many hundreds annually of our soldiers and sailors on that island till recently suffered; and whether, in view of the importance of this discovery in the annals of preventive medicine, inasmuch as at the present moment the disease had been entirely stamped out, he would consider the desirability of giving the thanks of the Government to the Royal Society for this instance of the successful application of British scientific research.—

enjoy the rest of the day. This fact, particularly in summer time, is very valuable considering the possibility of making excursions and attending outdoor amusements.

The Taxation of Secret Medicines and Cosmetics.

Vilmos Szigethy, a financial expert, has submitted a proposition to the Minister of Financial Affairs wherein he advises the taxation of all cosmetic and hygienic specialities. He shows that most of these substances are articles of luxury on which the manufacturers make immense profits, considering the fact that their production often costs less than the bottles and boxes wherein they are packed. The statistical returns of the last five years' imports of these articles prove that during this time £500,000 worth of perfumery and cosmetics and £200,000 worth of ready-made pharmaceutical preparations were imported into Hungary. The import increases from year to year. The demand is very large considering the fact that in Hungary itself cosmetics to the value of about £1,000,000 are manufactured. Szigethy quotes sad instances showing how detrimental these conditions are to the respectable druggists. He proposes to impose a tax on all cosmetics and secret medicines amounting to 25 per cent. of the sale price of the same. The proposal will be brought before the Legislature.

Calomel in the Treatment of Tuberculosis.

In a lecture delivered before a provincial medical society Dr. Bucsányi said that calomel has an almost specific action on phlyctenular conjunctivitis and on lupus tubercles. As it has such a particularly good effect on local tuberculous affections he has used it also for pulmonary tuberculosis in the form of inhalations. The method of administration is as follows: above a spirit lamp he puts a sheet of tin, and strews over it from 1 to 2 grammes of calomel (*via humida paratum*). In a few minutes the calomel is converted into a white, odourless vapour which is inhaled by the patient. These inhalations may be carried on for several weeks without the least harm to the patient. Dr. Bucsányi did not observe diarrhœa, salivation, or loss of appetite. He has applied this treatment in seven cases already and is satisfied with the results.

Feb. 13th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

United States and Canadian Methods of Health Inspection of Immigrants Compared.

IN a report recently issued by Dr. P. H. Bryce, of the Department of the Interior in the Canadian Government, this officer, who has had charge of the inspection of immigrants, states that the Canadian Act provides conditionally that otherwise desirable immigrants suffering from some curable disease may be detained for treatment, while the Act of the United States not only excludes persons suffering from loathsome and contagious diseases of a chronic type but further levies a fine upon the vessel carrying them if there is reasonable ground to suppose that the disease could have been detected before embarkation. In the case of Canada no immigrant shall be permitted to land in this country who is feeble-minded, an idiot or epileptic, or who is insane or has had an attack of insanity within four years. In this respect the United States Act is precisely the same. The chief difference in the laws of the two countries regarding the exclusion of undesirables is that the United States prohibits polygamists and anarchists from entering the country, while the immigration laws of Canada do not discriminate against these classes. The laws of Canada exclude the deaf, dumb, and blind, unless the immigrant so affected belongs to a family which will give security for his permanent support. From the United States are debarred persons who are undergoing a sentence for correction in their own country for crimes other than political, or whose sentence has been remitted conditional on their emigration. Canada is lax in this respect. The percentages of deportations in the two countries for the past nine years to the total immigrations show a higher ratio in the United States than in Canada. Of the British immigrants only 1 in 1003 is deported, while amongst those from the continent 1 in every 237 is deported from Canada. Of the latter the highest deportations are amongst Italians.

Annual Report of the Royal Victoria Hospital, Montreal.

There were admitted to the wards of the Royal Victoria Hospital during the year 1907 3398 patients, a decrease of 46 from the previous year. Of these 1994 were Protestants, 1071 were Roman Catholics, 290 were Hebrews, and 43 were of other faiths. The free patients numbered 1656 and the public ward patients 1280, and there were 462 private patients. Of the total number 2473 were residents of Montreal. The total days of hospital treatment aggregated 81,902, as against 73,993 for the previous year. The average number of days' stay in hospital per patient was 24·10, as against 22·04 for the previous year. On Jan. 1st, 1907, there were 224 patients in the hospital remaining from 1906, and during the year 3404 were discharged, of whom 1897 were well, 1002 were improved, and 165 were not improved, while 123 were not treated and 217 died. There remained in the hospital on Dec. 31st, 1907, 218. Of the 217 deaths 71 took place within 48 hours of admission. The death-rate for the year has been 6·81 per cent., or, if those dying within 48 hours of their admission be deducted the rate would be 4·58 per cent. In the 14 years during which the hospital has been in existence it has treated 36 524 patients. In the out-patient departments during 1907 there were treated 4156 patients, the number of visits of these aggregating 27,399 consultations. The income for the year amounted to $168,381, while the ordinary expenditure amounted to $146,610. The total cost per day per patient has been $1.79.

Retirement of the Dean of the Laval Medical Faculty.

Dr. Jean Philippe Rottot, for many years dean of the medical faculty of Laval University, Montreal, has retired from this honourable post. Dr. Rottot was born in 1825 and graduated from the old Victoria College, Montreal, and was admitted to the practice of medicine in 1847. In 1850 he was given the chair of botany at Victoria College, which he left in 1878 to enter Laval University. Two years after he succeeded Dr. Pierre Beaubien in the chair of pathology, and when the Notre Dame Hospital was founded he was made head of the clinical department. In 1891 Dr. Rottot was given the deanship of the medical faculty of Laval University, which he has retained until the present time. His departure from the University is deeply regretted by both professors and students.

British Association for the Advancement of Science in Winnipeg in 1909.

Considerable progress has been already made with the arrangements for the meeting of the British Association for the Advancement of Science in Winnipeg in 1909. This will be the fourth time in 70 years that the Association has met outside the British Isles. The first occasion was in 1884 when the meeting took place in Montreal; the second in Toronto in 1897; and the third in South Africa in 1905. The Dominion Government has promised a grant of $25,000 towards the expenses of the meeting and the local executive will collect $50,000 for the entertainment of the visitors. The meeting will probably be held on August 25th and following days. Professor M. A. Parker, University of Manitoba, Winnipeg, Manitoba, is the honorary local secretary.

Violent and Sudden Deaths in Montreal in 1907.

According to the official report of Coroner MacMahon of Montreal there were 785 deaths in that city due to violence in 1907. Altogether 83 persons were killed by railways, of which deaths 60 were due to steam railways and 23 to street cars. Fire was responsible for the deaths of 44 persons, including 17 children and one teacher in a school fire. There were 12 homicides, 27 suicides, and 53 drowning accidents. The sudden deaths were 217. An automobile was responsible for one death.

Feb. 6th.

ROYAL SOCIETY OF MEDICINE: THERAPEUTICAL AND PHARMACOLOGICAL SECTION.—A conversazione of this section to which ladies are invited, will be held in the Apothecaries' Hall, Blackfriars, E.C., on Tuesday, Feb. 25th, at 4.30 P.M. An address will be given by Dr. Harry Campbell on the Therapeutics of Diet; there will also be demonstrations of electrical apparatus, colour photography, and an exhibition of instruments, drugs, and foods. Admission will be by signature or card of a Fellow of the society or a member of the section.

Chemistry in the University of Copenhagen. Translated from the Danish by Katharine A. Burke, B Sc. Lond., Assistant in the Department of Chemistry, University College, London. Price 9*s.*

MITTLER, ERNST SIEGFRIED UND SOHN, Kochstrasse, 68–71, Berlin.

Medizinal-Berichte über die Deutschen Schutzgebiete-Deutsch-Ostafrika, Kamerun, Togo, Deutsch-Südwestafrika, Neu-Guinea, Karolinen, Marshall-Inseln und Samoa, für das Jahr 1905–06. Herausgegeben vom Reichskolonialamt. Price M.7.50.

ORANGE JUDD COMPANY, New York. (KEGAN PAUL, TRENCH, TRÜBNER AND CO., LIMITED, London.)

Practical Dairy Bacteriology. By H. W. Conn, Ph.D., Professor of Biology of Wesleyan University and Bacteriologist of the State Board of Health of Connecticut. *Price 6s. 6d.*

ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH, Sixty-sixth-street and Avenue A, New York, U.S.A.

interested in the welfare of Epsom College, which he did so much to promote.

Dr. Galton leaves a widow and five daughters. The funeral took place at Shirley cemetery on Feb. 11th. The ceremony was largely attended by old friends and patients and many medical men from London and his neighbourhood, amongst those present being Mr. Edmund Owen, Mr. Frederic Durham, Dr. Henry Hetley, Mr. J. B. Lamb (secretary of Epsom College), Mr. G. C. Parnell, Mr. J. Sidney Turner, and Mr. E. Reynolds Ray.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: —Dr. Martin Bloch, formerly assistant to the late Professor E. Mendel of Berlin, aged 41 years.—Dr. Ferdinand Albert Thierfelder, professor of general pathology and pathological anatomy in Rostock, aged 65 years.—Dr. Karl von Voit, professor of physiology in the University of Munich, at the age of 67 years.—Dr. A. Polotebnoff, formerly professor of dermatology in the St. Petersburg Military Medical Academy.—Dr. Adrian T. Woodward, formerly professor of gynæcology in the University of Vermont.—Dr. Sirus-Pirondi, formerly professor in the Marseilles Medical School.—Dr. Robert W. Taylor, formerly professor of the diseases of the urogenital organs in the New Yokr College of Physicians and Surgeons.—Dr. Hermann Matersdorf of Dresden, who is said to have been the senior member of the profession in Germany, at the age of 98 years.—Dr. Michael van Puteren, formerly *privat-docent* of children's diseases in the St. Petersburg Military Medical Academy.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—The Comitia of the Royal College of Physicians on Jan. 30th conferred Licences to practise upon the following gentlemen who had completed the Final Examination of the Examining Board in England in Medicine, Surgery, and Midwifery, and the Council of the Royal College of Surgeons conferred the Diploma of Member upon the same gentlemen on Feb. 13th:—

Alexander Charles Anderson, Cambridge University and St. Thomas's Hospital; Charles Ernest Anderson, King's College Hospital; Arthur George Atkinson, B.A. Cantab., Cambridge University and St. George's Hospital; Tobias Rustat Hemsted Blake, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Harry Blakeway, B Sc. Lond., St. Bartholomew's Hospital; Stanley Leemore Brimblecombe, St. Mary's Hospital; John Philip Buckley, B.A. Cantab., Cambridge and Manchester Universities; William Alexander Burr, M.D. Toronto, Toronto University and London Hospital; Howard James Barrell Cane, B.A. Cantab., Cambridge University and Guy's Hospital; Ernest Patrick Carmody, St. Bartholomew's Hospital; Arthur John Wellington Cunningham, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Sidney Trevor Davies, St. Bartholomew's Hospital; Bernard Day, B.A. Cantab., Cambridge University and St. George's Hospital; Arthur Ffolliott William Denning, Guy's Hospital; Alban Dixon, St. Mary's Hospital; John McDougall Eckstein, St. Bartholomew's Hospital; John Everidge, Durham University and King's College Hospital; Arthur Leslie Foster, Guy's Hospital; Herbert Gall, St. Bartholomew's Hospital; Eric Worsley Gandy, B.A. Cantab., Cambridge University and Westminster Hospital; Eric Gerald Gauntlett, King's College Hospital; William Gilliatt, Middlesex Hospital; Harold Delf Gillies, Cambridge University and St. Bartholomew's Hospital; Gathorne Robert Girdlestone, B.A. Oxon., Oxford University and St. Thomas's Hospital; Alexander Edward Gow, St. Bartholomew's Hospital; *John Lawrence Graham-Jones, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Archibald Hamilton, B.A. Cantab., Cambridge University and St. Mary's Hospital; Charles Thomas Hawkins, University College, Cardiff, and St. Mary's Hospital; Claud Anthony Holburn, Sheffield University; Nelson West Jenkin, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Gordon Ley, London Hospital; Edward Leslie Martyn Lobb, Guy's Hospital; Dermot Loughlin, London Hospital; Alexander Todd McCaw, New Zealand University and London Hospital; Donald Macrae, London Hospital; Claude Herbert Marshall, Guy's Hospital; John Birch Martin, Guy's Hospital; Thomas Mackinlay Miller, St. Bartholomew's Hospital; Roderick Joseph Graham Parnell, University College, Bristol, and King's College Hospital; Eustace Macartney Parsons-Smith, St. Thomas's Hospital; Hubert Pinto-Leite, B.A. Cantab., Cambridge University and St. George's Hospital; Horace John D'Arcy Gerard Price, Birmingham University; Robert Bernard Price, St. Bartholomew's Hospital; Joseph Francis Engledue Prideaux, University College Hospital; Edward John Joseph Quirk, Charing Cross Hospital; Percy Charles Raiment, London Hospital; Roland Waters Rix, St. Thomas's Hospital; Harold Trenchard Rossiter, St. Thomas's Hospital; Mulk Raj Sawhney, St. Bartholomew's Hospital; Francis Charles Searle, St. Bartholomew's Hospital; Leonard Whittaker Sharp, B.A. Cantab., Cambridge University and London Hospital; *Charles Harold Smith, M.B. Liverp., Liverpool University; Frank Harold Stephens, St. Mary's Hospital; Hugh Stott, Guy's Hospital; Gilbert Francis Syms, Guy's Hospital; Wilfrid Reginald Taylor, St. Mary's Hospital; Ernest William Toulmin, St. Mary's Hospital; Nusserwanji Hormasji Vakeel, Bombay University and St. Bartholomew's Hospital; Cuthbert Ferguson Walker, B.A., Royal University of Ireland, Galway, Belfast, and St. Mary's Hospital; Alan Geoffrey Wells, St. Mary's Hospital; Ernest Godfrey Wheat, Cambridge University and King's College Hospital; James Norman Wheeler, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Edward Barton Cartwright White, London Hospital; William Cecil Wigan, Oxford University and St. Bartholomew's Hospital; Cyril Oswald Oxford Williams, St. Bartholomew's Hospital; Rajaiya Robert Williams, L.R.C.P. & S. Edin., Edinburgh, Madras, and University College Hospital; John Samuel Williamson, St. Bartholomew's Hospital; and William Louis René Wood, L.S.A. Leeds University.

* Diplomas of M.R.C.S. were conferred upon these gentlemen on Jan. 16th.

Diplomas in Public Health have been granted to the following gentlemen:—

Robert Cecil Turle Evans, L.S.A., University College Hospital; Ernest Edward Scott Joseph Galbraith, L.R.C.P. & S. Edin., L.F.P.S. Glasg., Queen's College, Cork, and London Hospital; William Henry Hillyer, M.D. Durh., L.R.C.P., M.R.C.S., Vienna and St. Thomas's Hospital; Wharram Henry Lamplough, M.D., B.S. Durh., L.R.C.P., M.R.C.S., Durham University and St. Bartholomew's Hospital; Arthur Rieussett Littlejohn, L.R.C.P., M.R.C.S., St. Mary's and University College Hospitals; James Mair, M.B., C.M. Glasg., Glasgow University and London Hospital; Fairlee Russell Ozzard, Major, I.M.S., L.R.C.P., M.R.C.S., London Hospital; George Elliott Frank Stammers, Captain, R.A.M.C., L.R.C.P., M.R.C.S., University College, Bristol, and Royal Army Medical College; James Batson Stephens, M.B., B.S. *Lond.*, L.R.C.P., M.R.C.S., St. Mary's and University College Hospitals; and John Tate, L.R.C.P., M.R.C.S., University College Hospital.

The Council of the Royal College of Surgeons of England also conferred the Licence in Dental Surgery upon Harold Walker, Guy's Hospital, who has passed the examinations and complied with the necessary by-laws.

UNIVERSITY OF CAMBRIDGE.—A change in the regulations for the M.B. degree has been made and it has been decided to hold three examinations for the first M.B., two as at present in June and December and a third early in the October term. By this change a student who is well prepared will be able to pass the first M.B. on coming up and to begin on the courses in anatomy and physiology at once. Also a student who just fails to pass the examination in June will have a chance of passing in the following October instead of waiting till December.—The following degrees were conferred on Feb. 13th:—

M.D.—G. G. Ellett, Catharine.
M.B., *B.C.*—L. J. Austin and D. W. Roy, Sidney Sussex.
M.B.—D. Holroyde, Trinity.

UNIVERSITY OF LONDON.—At the Intermediate Examination in Medicine held in January the following candidates were successful:—

John Wroth Adams, St. Bartholomew's Hospital; Francis Cooke Alton, St. Thomas's Hospital; Kathleen Jane Armstrong, London (Royal Free Hospital) School of Medicine for Women; Edwin Augustus Attenborough, London Hospital; †Cyril Banks, University of Sheffield; Maurice Beddow Bayly, Charing Cross Hospital; Claude Alexander Birts, University College; Kenneth C. Bomford, St. Bartholomew's Hospital; Kenneth James Charles Bradshaw, University of Liverpool; Frederick Leslie Brewer, University College; †Edward Spencer Calthrop, Charing Cross Hospital; Sydney James Clegg, Victoria University of Manchester; Guy Barton Cockrem, Guy's Hospital; Ardeshir Koyaji Contractor, University College; Grace Marion Cordingley, London (Royal Free Hospital) School of Medicine for Women; Goronwy Meredith Davies, St. Thomas's Hospital; Frederick Adolph Dick and John Adamson Edmond, Guy's Hospital; Reginald Robert Elworthy, Westminster Hospital; Thomas Charles Cann Evans, St. Mary's Hospital; Archibald Ferguson, St. Bartholomew's Hospital; Violet Evangeline Fox, London (Royal Free Hospital) School of Medicine for Women; Walter Egbert Fox, Guy's Hospital; Thomas Woodcock George and Charles Gibson, London Hospital; Katherine Anne Gill and Edith Croft Goodison, London (Royal Free Hospital) School of Medicine for Women; Charles D'Oyly Grange, University of Leeds; Hugh Arrowsmith Grierson, University of Liverpool; Henry Pollard Hacker, B.Sc., King's College; Arthur William Havard, London Hospital and University College, Cardiff; Reginald Melville Hiley, University College, Bristol; Henry Hingston, King's College; Harrie Marguerite Hood-Barrs, London (Royal Free Hospital) School of Medicine for Women; Edward Leslie Horsburgh, Victoria University of Manchester; Thomas Lewis Jones, Guy's Hospital; *†Norman Claudius Lake, Charing Cross Hospital; Frederick Norton H. Maidment, London Hospital; Kenneth D. Marriner, St. Thomas's Hospital; Guy Matthews, King's College; James Menzies, St. Mary's Hospital; Raymond Montgomery, University of Leeds; Adrian Leonard Moreton, St. Bartholomew's Hospital; George Edmund Eyre Nicholls, Victoria University of Manchester; Alexander Croydon Palmer, London Hospital; Helen Lawson Peacock and Cicely May Peake, London (Royal Free Hospital) School of Medicine for Women; Edward Austen Penny, Guy's Hospital; Morna Lloyd Rawlins, London (Royal Free Hospital) School of Medicine for Women; Arnold Renshaw, Victoria University of Manchester; Harold Ferdinand Renton, University of Leeds; Maude Margaret Richards, London (Royal Free Hospital) School of

William Church, in replying, praised the results achieved by societies like the West London Medico-Chirurgical Society and pointed out that it was no part of the scheme of the Royal Society of Medicine to absorb societies such as theirs. Mr. Arbuthnot Lane, who also replied to this toast, concluded his remarks by proposing the health of the chairman, and that gentleman, in the course of acknowledging the toast, thanked the officers of the society for the help which they had accorded to him in his duties as President.

ROYAL LONDON OPHTHALMIC HOSPITAL (MOORFIELDS EYE HOSPITAL).—The annual general meeting of governors of this charity will be held on Tuesday, Feb. 25th, at 3 o'clock, at the Mansion House, by permission of the Lord Mayor, who has consented to preside. Lord Avebury, Sir Charles Wyndham, Dr. Hermann Adler, and Mr. H. Curtis Bennett have promised to speak in support of the hospital.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD.—It will be remembered that this board was constituted in 1904 with the approval of the governing bodies of University College, King's College, and the East London College, for the purpose of holding a combined annual examination for entrance scholarships and exhibitions tenable at those Colleges, and that the examination may be made use of by other bodies for the award of scholarships and exhibitions, subject to arrangement with the board. We are asked to state that the board will hold a combined examination for 20 scholarships and exhibitions in classics, languages, literature, history, science, and mathematics, tenable at University College, King's College, and the East London College, on May 12th and following days. No candidates will be admitted to the examination unless they have passed the London University matriculation or an equivalent examination and are under the age of 19 years on Oct. 1st, 1908. The total value of the scholarships offered exceeds £1700. Most of them are open to students of both sexes. Full particulars and forms of entry may be obtained from the secretary of the board (Mr. Alfred E. G. Attoe), University College, Gower-street, London, W.C.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The following have been elected by the council to be presidents of sections at the meeting of the association to be held in Dublin in September next under the general presidency of Mr. Francis Darwin, F.R.S.:—Section A (mathematical and physical science), Dr. W. N. Shaw, F.R.S., director of the Meteorological Office; Section B (chemistry), Professor F. S. Kipping, F.R.S., professor of chemistry in University College, Nottingham; Section C (geology), Professor J. Joly, F.R.S., professor of geology and mineralogy in the University of Dublin; Section D (zoology), Dr. S. F. Harmer, superintendent of the University Museum of Zoology, Cambridge; Section E (geography), Major E. H. Hills, C.M.G.; Section F (economic science and statistics), Lord Brassey; Section G (engineering), Mr. Dugald Clerk, M.Inst. C.E.; Section H (anthropology), Professor W. Ridgeway, professor of archæology in the University of Cambridge; Section I (physiology), Dr. John Scott Haldane, F.R.S., University reader in Physiology at Oxford; Section K (botany), Dr. F. F. Blackman, F.R.S., professor of botany in the University of Leeds; and Section L (educational science), Professor L. C. Miall, formerly professor of biology in the University of Leeds. Invitations to deliver evening discourses during the meeting of the Association at Dublin have been accepted by Professor H. H. Turner, F.R.S., Savilian professor of astronomy at Oxford, who will take as his subject "Halley's Comet"; and Professor W. M. Davis, of Harvard University, whose lecture will be entitled "The Lessons of the Colorado Cañon."

LONDON FEVER HOSPITAL.—The annual general meeting of the governors of this hospital was held at the Hotel Victoria, Northumberland-avenue, on Feb. 14th the chair being taken by the Right Hon. Lord Balfour of Burleigh, K.T., the president, who said he thought that he could fairly ask the meeting to express their appreciation in this regard because they had had a satisfactory year, 781 patients having been admitted during the year, which with 71 brought forward made a total of 852 patients treated for all diseases, this number being 250 more than the average of the last 20 years. Notwithstanding the increase of numbers the average rate of mortality in scarlet fever had been down so low as 1·50 lower than the previous years. Although during the rebuilding of the hospital they had had to refuse 35 patients, they were now able fully to meet the demands made upon them. 216 patients had been treated free in virtue of the subscriptions of private governors and managers of business houses, 476 had paid the ordinary fee of 3 guineas, 51 had paid 3 guineas a week in private rooms, and 38 had had their like fees remitted owing to their having established their inability to meet the charge. 72 of those who were charged 3 guineas had supplemented their fee not only by expressions of gratitude for the kindly care and attention which they had received but had sent sums totalling £227 in amounts varying from 1 guinea to £25. He appealed to the public for a continuation of their support which had hitherto been so generously given. He was afraid the completion of the new wing for measles would have to wait until further funds were forthcoming. The adoption of the report (which had been previously read by Dr. Sidney P. Phillips, the senior physician, and moved by Sir Shirley F. Murphy, medical officer of the London County Council) was carried unanimously. On the motion of Mr. Edward Norman, Lord Balfour was re-elected as president for the ensuing year, the vice-presidents, treasurer, honorary secretary, and members of the committee being elected. A vote of thanks (proposed by Mr. Mead) to Lord Balfour for presiding concluded the proceedings.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Children's Bill.

MR. HERBERT SAMUEL, when he introduced the Children's Bill in the House of Commons, was prevented by the exigencies of time from explaining in detail many parts of this comprehensive measure. The text of the Bill is now available and it is possible to fill in with precision its various proposals. To recapitulate them would be a lengthy process, for the Bill contains 119 clauses, many of them of a complicated character. However, several points which were alluded to in this column last week may be further elaborated. For instance, it was mentioned that under the measure a penalty was proposed for exposing children to the risk of burning. The clause dealing with this matter lays down that if a person who has the custody or care of a child under the age of seven years, "allows that child to be in any room containing an open fire grate not sufficiently protected to guard against the risk of the child being burnt or scalded, and without taking reasonable precautions against that risk, and if by reason thereof the child is killed or suffers serious injury," he shall on summary conviction be liable to a fine not exceeding £10. This section does not extinguish the liability of such person to be proceeded against by indictment for any indictable offence. The penalty for causing the death of an infant under three years by overlying it is also a fine not exceeding £10. If the offender is proved to have been under the influence of drink the fine may amount to £25 and the court has the power to impose an alternative or an additional sentence of imprisonment for a term not exceeding three months if the offence is accompanied by aggravating circumstances.

Juvenile Smoking.

Six clauses in the Children's Bill deal with the Prohibition of Juvenile Smoking. An ascending scale of penalties for selling tobacco to children and young persons is set out. The first offence may be visited with a fine not exceeding £2 and the second with a fine not exceeding £5, but the third offence makes the offender liable to a penalty of £20. The words of the section have been carefully chosen and any person is liable to conviction if he "sells or gives to a person apparently under the age of 16 years any cigarette or cigarette papers, whether for his own use or not, or sells or gives to such a person any other tobacco which he knows or has reason to believe is for the use of that person." Constables, park-keepers, and persons authorised by special by-laws are to seize cigarettes and tobacco in the possession of "any person apparently under the age of sixteen" who is found smoking or about to smoke in any street or public place. A penalty is also proposed to be laid on the juvenile smoker himself. This clause, which deals directly with the evil, is of such importance that it may be quoted *in extenso*. It runs thus: "If a child or young person smokes in a street or public place, or purchases or has in his possession, whether for his own use or not, any cigarettes or cigarette papers, or purchases or has in his possession for his own use any other tobacco, he shall be liable on summary conviction in the case of a first offence to be reprimanded, and in the case of a second offence to a fine not exceeding 5s., and in the case of a third or subsequent offence to a fine not exceeding 10s." The phraseology of this section of the Bill is worthy of attention, as a distinction is drawn between the terms "cigarette" and "other tobacco." It seems to be the proposal of the Home Office that the actual possession of a cigarette, quite apart from the intention to smoke it, shall be an offence in a person under the age of

Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnières, Paris.

Mr. HALDANE replied: I am aware of the great service rendered by the commission in question. The commission's investigations and the adoption of preventive measures as the outcome of its recommendations have been followed by the practical disappearance of Malta fever from the garrison of the island. I think that the Royal Society is well aware how genuine is the appreciation of the Government. We owe much to the Royal Society's Commission for the successful issue of this remarkable investigation and for the excellent results which have followed. These results illustrate the enormous importance of bringing science into our business of government.

The Belfast Health Commission.

Mr. DEVLIN asked the Chief Secretary to the Lord Lieutenant of Ireland whether any report had yet been received from the Health Commission which recently sat in Belfast; or, if not, when was the report likely to be published.—The Attorney-General for Ireland (Mr. CHERRY) replied in the absence of Mr. BIRRELL: The report has not yet been received, but I am informed by the Chairman of the Commission that it may be expected early next month.

Milk-blended Butter.

Mr. O'SHAUGHNESSY asked the honourable Member for South Somerset, as representing the President of the Board of Agriculture, whether he could say under what name was milk-blended butter sold with the approval of the Board of Agriculture, in accordance with the Butter and Margarine Act, 1907, when it contains more than 16 per cent. and under 24 per cent. of water; and whether, under the Act, there was any change in the description of margarine when offered for sale to the public.—Sir EDWARD STRACHEY replied: 19 names have up to the present time been approved by the Board for milk-blended butter. The law as to the manner in which margarine is to be described was amended by Section 8 of this Act, to which the honourable Member refers.

Milk Legislation.

Mr. COURTHOPE asked the President of the Local Government Board whether, in view of the intention of the Government to introduce general legislation on the subject of the milk-supply, he would move instructions to the committees on all private Bills containing milk clauses that such clauses be struck out.—Mr. BURNS wrote in reply: It does not seem to me that the course proposed could well be adopted. I think that the best plan will be that the clauses should for the present be retained on the understanding that they will be subject to reconsideration at a later stage in the event of a public Bill being passed.

Tuberculosis in Frozen Meat.

Mr. COURTHOPE asked the President of the Local Government Board whether he was aware that frozen beef from the Argentine had recently been seized in Hull affected with glandular tuberculosis, although accompanied by the official label of the Argentine Government certifying that the meat was sound; and what steps he proposed to take to safeguard the health of the community from such occurrences in future.—Mr. BURNS furnished the following written reply: The answer to the first part of the question is in the affirmative. Regulations under the Public Health (Regulations as to Food) Act, 1907, are in preparation and will, I hope, soon be issued to confer additional powers on port sanitary authorities and to enable them to deal suitably with any diseased meat which may be detected on arrival in this country.

TUESDAY, FEB. 18TH.

Horse Meat and Sausages.

Mr. RICHARDSON asked the President of the Local Government Board whether he had any official information as to the number of worn-out horses sent from Nottingham and Worksop to the continent, and as to whether these animals were there converted into sausages and then imported into this country for consumption as human food, if so, could he say to what port on the continent they were exported, and what proportion of this sausage was consumed in this country.—Mr. BURNS answered: I have no official information as to the number of worn-out horses sent from Nottingham and Worksop to the continent. I have not met with any definite evidence pointing to the importation into this country of sausages prepared from horses, though it is sometimes alleged that sausage meat imported in bulk contains horse meat. I have the subject of the importation of sausage meat under consideration in connexion with the regulations which I am preparing under the Public Health (Regulations as to Food) Act of last session.

Soldiers and Tuberculosis.

Mr. SUMMERBELL asked the Secretary of State for War what action he proposed to take in regard to soldiers suffering from tuberculosis in view of the findings of the Select Committee appointed to go into the matter.—Mr. HALDANE replied: The recommendations of the Select Committee have been recently considered by the Government as a whole. The decision is that, however desirable the special provision recommended by the committee in the case of soldiers discharged from the army because of tuberculosis, it is impossible to justify the assumption of this new kind of obligation by the State unless it is extended to other services as well as the army, and possibly more widely still. The question thus raised becomes one of great gravity and cannot be decided by any single department.

The London County Council and Inebriate Institutions.

In answer to Mr. CHARLES ROBERTS, Mr. GLADSTONE, the Home Secretary, wrote that he had received with much regret a letter from the London County Council stating that the Council did not see its way to renew its contracts with the national institutions for the care and reformation of inebriate persons. The accounts of seven out of the eight institutions of this kind in full working order during 1906 showed a maintenance cost varying from 10s. 4d. to 14s. per inmate per week, but the eighth, "Farmfield," managed by the London County Council, was not conducted at less than a weekly rate of 19s. 6d. per head. It was felt that 14s. per week should be considered the total amount required for maintenance and that the managers of reformatories should be induced to bring down their expenses to that sum per head. In furtherance of the view that the segregation of inebriates relieved imperial and local funds about equally, it was decided that the Government contribution should be reduced from 10s. 6d. to 7s. to correspond with the 7s. provided by local authorities. This reduction had been accepted as reasonable by the managers of reformatories except in the case of the London County Council. In May last the council decided to withdraw its contract with the national institutions and restrict its work under the Inebriates Act to that carried on at Farmfield for 100 cases. The right honourable gentleman added in conclusion that a few vacancies at Farmfield would probably be available from time to time, but these would be so few as practically to render the Act useless so far as London was concerned, and the step taken by the council would, involve reversion to the discredited system of short and repeated terms of imprisonment as the only means of dealing with female inebriates but no power existed by which the council could be compelled to reverse its decision or make other adequate provision for the needs of cases committed from within its administrative area.

WEDNESDAY, FEB. 19TH.

The Royal College of Surgeons of England.

Sir WILLIAM COLLINS asked the Prime Minister whether he would state what action had been taken by the Lord President of the Council in regard to the memorial which was presented to the Prime Minister in the session before last on behalf of Members of the Royal College of Surgeons of England, asking him to take such steps as might secure to Members some voice in the management of the College and its property; and what reply had been received from the Council of the College to representations made to them by the Lord President.—Sir HENRY CAMPBELL-BANNERMAN wrote in reply: It is a matter of common knowledge that in reply to the different deputations which he received, the Lord President expressed the general sympathy of the Government with the objects of the memorial; but the Council of the Royal College appear to maintain the rigour of their attitude on the subject.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapst, Asnières, Paris.

Ipswich Education Committee.—Assistant School Medical Officer. Salary at rate of £150 per annum.

Lanark County Council.—Bacteriologist. Salary £250 per annum.

Liverpool, David Lewis Northern Hospital.—House Surgeon, also House Physician. Salary £60 each per annum, with residence and maintenance.

Manchester Children's Hospital, Pendlebury.—Junior Resident Medical Officer, unmarried. Salary at rate of £80 per annum, with board and lodging.

Manchester Royal Infirmary and Dispensary.—Honorary Assistant Gynæcological Surgeon.

Metropolitan Asylums Board.—Assistant Bacteriologist. Salary £300, rising to £350, per annum.

Metropolitan Hospital, Kingsland-road, N.E.—Casualty Officer. Salary at rate of £150 per annum.

Middlesbrough Education Committee.—Assistant to the Medical Inspector of School Children. Salary £300 per annum.

Middlesex Hospital, W.—Registrar to the Cancer Wards, also Scholar in the Cancer Research Laboratories. Salary of the Registrar £40 per annum and of the Research Scholar £60 per annum.

National Hospital for the Paralysed and Epileptic, Albany Memorial, Queen-square, Bloomsbury.—Assistant Pathologist. Salary 50 guineas per annum. Also Resident Medical Officer. Salary £100 per annum, with board and apartments.

Newport (Mon.) Education Committee.—Assistant Medical Officer of Health and Medical Inspector of Schools. Salary £225, rising to £275.

Norwich, Norfolk and Norwich Hospital.—Assistant House Surgeon for six months. Salary £20, with apartments, board, and laundry.

Nottinghamshire Education Committee.—School Medical Officer. Salary £300 per annum, and travelling expenses.

Plymouth Education Authority.—School Medical Officer. Salary £250 per annum.

Poplar Hospital for Accidents, Poplar, E.—Assistant House Surgeon. Salary at rate of £80 per annum, with board and residence.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Resident Medical Officer. Salary at rate of £50 per annum, with board, residence, and washing.

Royal Berkshire Hospital.—House Physician. Salary £80 per annum, with board, lodging, and washing. Also Assistant House Surgeon. Salary £60 per annum, with board, lodging, and washing.

Royal Navy, Medical Department.—Examination for not less than 15 Commissions.

Salisbury Infirmary.—Assistant House Surgeon, unmarried. Salary £50 per annum, with apartments, board, and lodging.

Sunderland Infirmary.—House Physician. Salary £80 per annum, with board, residence, and washing.

Throat Hospital, Golden-square, W.—House Surgeon. Salary £75 per annum, with residence, board, and laundry.

West London Hospital, Hammersmith-road, W.—Two House Physicians and three House Surgeons for six months. Board, lodging, and laundry allowance provided.

Western General Dispensary, Marylebone-road, N.W.—Junior House Surgeon. Salary at rate of £80 per annum, with board, lodging, and washing.

Worcestershire, Barnsley Hall Asylum, Bromsgrove.—Second Assistant Medical Officer. Salary £160 per annum, with quarters, board, washing, and attendance.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Foyers, in the county of Inverness; at St. Germans, in the county of Cornwall; at Dulais Valley, in the county of Glamorgan; at Llandrindod Wells, in the county of Radnor; at Newcastle, in the county of Limerick; and at Ovoca, in the county of Wicklow.

Births, Marriages, and Deaths.

BIRTHS.

Archer.—On Feb. 15th, at Hamlet Court-road, Westcliff, the wife of Archibald Archer, L.D.S. Eng., of a son.

Dunne.—On Feb. 11th, at 20, Trent Boulevard, West Bridgford, Nottingham, the wife of Arthur Briggs Dunne, M.B., B.C. Cantab., D.P.H. Lond., of a daughter.

Hedley.—On Feb. 13th, at 56, Hans-place, S.W., to Dr. and Mrs. Edward Hedley—a daughter.

Wakefield.—On Feb. 10th, at Norwood-hill, Charlwood, near Horley, Surrey, the wife of Christopher Frank Wakefield, M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

Heath—Addison.—On Feb. 14th, at St. Paul's Church, Avenue-road, Regent's Park, Philip Maynard Heath, M.S., F.R.C.S., to Dorothy Mary Rosamond, only daughter of Joseph Addison.

Jenkins—Loveridge.—On Feb. 16th, at the Cathedral, Shanghai, Herbert Stanley Jenkins, M.D. Lond., F.R.C.S. Eng., of Sianfu, Shensi, North China, and Clifton, Bristol, England, to M. L. (Daisy), eldest daughter of Thomas Loveridge, Llandaff, Cardiff.

DEATH.

Harvey.—On Feb. 12th, at Westbury-on-Trym, Bristol, Alice Mary, wife of Alfred Harvey, M.B., and daughter of the late John Bassett, M.D., of Birmingham.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE UNIVERSITY OF LIVERPOOL IN ITS RELATION TO PUBLIC HEALTH.

A correspondent writes: "There is no University in Britain so deeply indebted to the local city council as that of Liverpool. The University was almost called into existence in 1880 by the municipal council which presented a site and buildings for the new institution worth £30,000; its annual grant in aid has risen to the sum of £11,700; the Lancashire, Cheshire, Bootle, and Birkenhead councils also contribute a total yearly sum of £2300. Whenever additional funds have been required, and the occasions are numerous, the city council has always lent moral support; indeed, it is not too much to say that the relation between council and University is a filial one. But the obligations are not all on one side; the University undertakes a great deal of the work that a higher conception of civic duty has compelled modern municipalities to assume. Liverpool University boasts that in every department a considerable body of students continue the work of original research under the guidance of the professors. The work of the School of Tropical Medicine is widely known. But, in addition, the useful work of analysing daily and systematically the water of the city is performed in the laboratories of the University; considerable quantities of food and beverages are sent to the authorities for bacteriological analysis and report on adulteration. Diseases of animals are studied and reported on. It is not very long since a mysterious disease broke out in a factory. Its cause could not be ascertained until the botanical department of the University discovered that a poisonous wood had been used in the equipment of the factory. Analyses of this kind could not be thoroughly and scientifically performed without great expense to the local authority but for the coöperation of the University. All the county and city councils named have a right to the services enumerated. The University also offers direct and important service to the whole of the local medical profession by means of its bacteriological and pathological departments."

"LOCAL HOSPITALS" IN AMERICA.

The *Nursing News* of Feb. 15th contains an interesting article by Miss A. L. Pringle, formerly matron of the Edinburgh Royal Infirmary, on the subject of "Local Hospitals" in America. These useful institutions are indispensable to a country where so many people make their homes in lodging- and boarding-houses with no conveniences for sick nursing. They do not find a match in our cottage hospitals, or in our nursing homes, but are something more on the lines of small and well-equipped general hospitals, in which the patients pay for their support according to their means and are attended by the practitioners of the neighbourhood, an arrangement which is alike beneficial to patients and medical men. When there is any deficit in the funds it is made up by public appeal and the benevolence of individuals, and the ladies in the various districts interest themselves practically in the hospital's welfare. The appointments and manner of serving meals approximate to that to which the patients are accustomed at home, and the patients altogether have more latitude than do the inmates of our hospitals for the sick poor. Miss Pringle draws a delightful picture of one of these hospitals in Massachusetts which "stands just outside the town on a shelf of high ground, the wooded summit of which rises behind it uncultivated, unfenced, a foot-hill of the beautiful range inclosing the valley of a famous river. In front are flowers and a lawn, but otherwise all round is rough woodland, and in favourable weather the patients lie out there in piazzas or in tent wards, enjoying the trees, the birds, and the sky as freely as if they were in the back-woods."

THE HOUR OF BIRTH.

Dr. F. W. Lynch of Chicago has lately (December, 1907) published in *Surgery, Gynæcology, and Obstetrics* an analysis of the hour of birth in 1503 full-term spontaneous labours at Johns Hopkins Hospital. He concludes that the theory that most births occur during the night is erroneous and that parturition is distributed fairly evenly throughout the 24 hours, though the variations between 7 P.M. and 7 A.M. showed 4 per cent. more births than in the other 12 hours, in which the variation was less than 0·5 per cent.

THE REMOVAL OF TATTOO MARKS.

In a recent number of *La Nature* an account is given of Dr. Everard's method of removing tattoo marks. A blister is raised over the whole of the affected area by means of a plaster. The epidermis is then removed, a solution of cocaine is applied, and the tattoo marks are effaced by a thermo-cautery. The cautery is passed over the entire area until it assumes a brown appearance, like that of wood in pyro-engraving. In this way all traces of indigo or carmine disappear. The parts are then dressed with an ointment containing 10 per cent. of salicylic acid. On the third or fourth day a scab may be removed and the pigmentation will have disappeared. An evident scar on section. Thus its appearance at operation is not always conclusive. When examined in cross sections it shows a varied disarrangement of its internal structure, fissures, hæmorrhages, and dislocation of the grey matter being frequent. Later the *dura mater* becomes bound down to the cord by adhesions which also form between the dura mater and the bony canal. The cord appears smaller than normal, perhaps one-third of its original size. It is also well recognised that injury to the spinal cord without detectable injury, even at necropsy, to the vertebral column may occur and is not rare. The usual symptoms are said to be due to hæmatomyelia, though Spiller also describes a condition which he calls traumatic myelitis. This is characterised by nerve cell and fibre degeneration, round cell infiltration, proliferation of neuroglia, congestion of blood-vessels, and miliary hæmorrhages. It is, however, impossible to diagnose clinically between these two conditions.

Frequency.—In one-third of the lesions affecting the vertebral column the spinal cord escapes all injury. This freedom from injury is seen most frequently in the cervical region for reasons already given. Children more often escape injury to their cords than do adults. The cervical and lumbar regions contain about one-half of the cases of fracture, the dorsal region the other half. Most of the dorsal fracture dislocations involve the eleventh or twelfth vertebra, this giving rise to a lumbar type of paralysis. Neurologically considered, the majority of cases of injury to the spinal cord from fracture-dislocations are either the cervical type, which includes the first dorsal segment, or the lumbo-sacral type, including the cauda equina. Surgical statistics show the latter to be much more frequent.

Clinical types.—From a clinical point of view of cases injury to the vertebral column may be divided into two main classes: (1) those in which the functions of the spinal cord are not interfered with; and (2) those in which there is more or less interference with the functions of the spinal cord, with or without obvious injury to the vertebral column. So that the first question to be decided when investigating cases of injury in this region is: Is the spinal cord affected? And if so, to what extent is it damaged? The first question can usually be answered without difficulty. The second not so, because it opens up the subject, to be discussed later, as to whether it can be definitely decided that the symptoms present are due to a total or partial transverse lesion.

Three types of cases may, I think, be recognised clinically: (1) those in which it is perfectly clear from the position of the fractured vertebræ that the cord must be completely severed; (2) those in which it *cannot* be decided definitely without waiting for some time whether the lesion is complete or partial; and (3) those in which it can be definitely stated that the lesion is a partial one. In the first class are included those cases in which the displacement is so great that the inferior surface of the body of the dislocated vertebra lies upon the anterior surface of the body of the vertebra next below it. It is obvious that when the bones are forced into this position the spinal cord must have been cut completely across. The position of the fragments in these cases can only be definitely determined by a skiagram, though the deformity is always greater than in other cases. The second class includes the largest number of cases. They are such that only by their persistence can the symptoms be said to be due to a total transverse lesion. The third class are those in which the symptoms point undoubtedly to a partial transverse lesion. They are chiefly seen in distortions, unilateral dislocations, isolated fractures of spinous processes or arches, and pressure fractures of the vertebral bodies.

Diagnosis between partial and total transverse lesions.—Is it ever possible to decide definitely from a study of the symptoms in cases of fracture-dislocation of the spine that the lesion in the spinal cord is complete? Or, in other words, is there any symptom-complex which establishes beyond a doubt that the injury to the cord is irremediable? It may at once be said that there *is not*. It is only by their persistence over a considerable length of time that the symptoms can establish the fact that the spinal cord lesion is a complete one. Certain symptoms, to which the unfortunate term "classical" has been applied, have been stated to denote always that the lesion is a complete one. Let me repeat that it is only by their persistence that they can do so. Their onset certainly does not preclude the possibility of the functions of the cord being restored, if not wholly, at any rate to a certain degree at least. What are these so-called classical symptoms that are usually held to point to a complete transverse lesion?

It will be well before answering this question to refer to those symptoms which undoubtedly indicate a partial lesion. These include any motor power below the lesion, any sensation, such as pain, numbness, cramps, of distension of the bladder and rectum, abdominal pain, or any sense of position. Pain felt in the hyperæsthetic zone upon *severe irritation of the paralysed parts*, even in the presence of total anæsthesia, determines that the lesion is a partial one. The deep reflexes may be abolished at the outset in partial lesions, to return later, and even become exaggerated. Return of the deep reflexes at any time decides that the lesion has been a partial one. Incomplete or limited anæsthesia, or anæsthesia of unilateral distribution, anæsthesia limited to regions far below the level of the lesion, and modification of the anæsthesia at different levels, all point to a partial lesion. In partial lesions sensation in the bladder and rectum may be retained, even though voluntary evacuation is impossible. Slow onset of paralysis or any sign of improvement points to a partial lesion. It may be said that symptoms referable to vasomotor disturbances are variable and confusing. Usually corresponding in extent to the motor paralysis, there is paralysis of vaso-constrictor fibres. This causes a rise in the superficial temperature of the lower extremities, due to dilatation of the subcutaneous vessels. Later this is replaced by coolness, or even marked coldness, of the extremities.

Turning now to a consideration of the symptoms which are *said* to indicate a total transverse lesion, these include total paralysis of motion and sensation, the anæsthesia being abruptly delimited, and surmounted by an area of hyperæsthesia. According to Kocher, below the hyperæsthetic area there often appears a strip of thermanæsthesia and analgesia, though this dissociation is not necessarily limited to the level of the lesion. Total loss of deep reflexes, priaprism, and paralysis of the bladder and rectum make up the picture as usually described of a total transverse lesion. As a result of a total transverse lesion the voluntary muscles below the lesion are all equally affected. They become flaccid, waste rapidly, and their faradic excitability lessens, rapidly at first, then more slowly, and, finally, it may be lost. The deep reflexes are permanently abolished and the sphincters lose their tone.

A differentiation should be made between an anatomical and a physiological total transverse lesion. For complete physiological abolition of function may occur without actual destruction of the nerve elements involved, and these may recover more or less completely. "When there is recovery from a total physiological transverse lesion the first sign of that recovery is the return of the knee-jerk and the gradual change from the flaccid to the spastic stage. Sensibility returns in the order, touch, pain, temperature, and the lowest sacral segments usually become sentient before the others. The first sign of this often is that the patient becomes conscious of the act of micturition or of catheterisation or of distension of the bladder during the routine lavage. Voluntary power returns in the flexors earlier than in the extensors, flexion of the toes being almost invariably the earliest voluntary movement possible. In cases where recovery is complete the plantar reflex does not resume the flexor type for some time after the patient has completely recovered the use of the lower limbs, the extensor response being the last of all the spastic signs to disappear." (James Collier.)

Complete motor paralysis and anæsthesia do not prove that the lesion is a total one, since recovery may follow their onset in pressure lesions. Though the knee-jerks be abolished at first they may return after a lapse of time, so that there absence denotes nothing in favour of a complete lesion. Priapism is not so frequent a symptom as would appear from text-books. Collier met with it in his series of cases only in connexion with partial lesions. He thinks that its presence signifies that the lesion is partial. None of these symptoms alone, nor all of them together, can be held to be pathognomonic of a total transverse lesion. Only their *persistence*, without variation, can be said to be so. And this persistence must last for some considerable time before a definite conclusion can be arrived at.

Regeneration.—The question of regeneration is a most important one in spinal cord pathology. It has been the opinion of most investigators that such regeneration in man does not take place. The report of the Stewart-Harte case, together with one by Fowler, has recently reopened the whole controversy. Both were cases in which suturing of the spinal cord, completely severed by a pistol bullet, was followed by a reported remarkable degree of recovery.

its full extent again and that pulsation returns (this is only possible where the cord has not been completely destroyed).

It is sometimes advanced as an argument that in operation there is a danger of interference in cases where spontaneous cure would result if the patient were left alone. I would reply by saying that if operation be not done and compression be allowed to continue a degeneration will assuredly result which will be as serious as though the cord had been destroyed by the original injury. Under like conditions life will not be endangered by the operation beyond an amount of risk constantly undertaken in less serious conditions, provided the initial shock due to injury has passed off. To this may be added an additional danger in those cases where the lesion is in the cervical region, with consequent paralysis of intercostal respiration. But even here, with a skilled anæsthetist and a practised operator, the risk is reduced to a minimum. The dangers of the operation are very slight therefore compared to the possible benefit to be derived therefrom.

Will any benefit result from the operation? Let us first consider what the operation may be expected to do. Briefly, it will relieve pressure, or, at any rate, remove any doubt as to whether continued pressure exists. Degeneration as a result of pressure appears within four days. If the spinal cord be not totally destroyed continued pressure may succeed in completing its destruction. Therefore the operation is indicated: (1) to relieve pressure from depressed or displaced fragments of bone; (2) to relieve pressure from blood clot or from extensive hæmorrhage, either extra- or intra-dural; (3) to relieve pressure and prevent further destruction from œdema by enlarging the constricted bony canal; and (4) to remove the future danger of pressure from exudate and inflammatory thickening. No operation will restore a cord in which complete transverse section has taken place. Therefore we are brought back to the one question, upon the answer to which hangs the whole subject of operation: Are there any symptoms by which we can in a reasonable time determine *beyond a doubt* the presence of a complete transverse section of the spinal cord? If there are not—and I believe there are not—then should not such a conclusion urge us—nay, compel us—to give our patient the benefit of an operation which experience shows neither materially endangers his life nor adds to his discomfort but lessens his pain? It will at least allow us to determine the exact nature and extent of the lesion and to place the cord under the most favourable conditions for recovery of function, if recovery be possible.

In respect to the question of operation in these cases surgeons have been divided into three classes: those who advocate operation in every case of injury in which cord symptoms are present; those who advise operation in selected cases; and those who abstain completely from operation. To those who would operate upon selected cases I would say, as Walton does, surely, "instead of selecting the occasional case for operation, we should rather select the occasional case in which operation is contra-indicated," by profound shock, high and rising temperature, and the obvious onset of dissolution. To those who abstain from operation completely I would put this question: May we not by operation often save a life or rescue a patient from a helpless condition of a most disabling character? If so, then surely the onus of proof lies upon the conservatism of those who refuse a sufferer this one chance of relief.

MEDICAL INSPECTION OF SCHOOL CHILDREN.—At the annual meeting of the Gloucestershire Poor-law Association, held on March 7th, Mr. J. D. Birchall read a paper on the Medical Inspection of School Children, and after some discussion a motion was carried unanimously stating that the work of medically inspecting the school children should be carried out by and under the medical officers of health.

THE CLINICAL SYMPTOMS OF THE CASES OF EPIDEMIC CEREBRO-SPINAL MENINGITIS

ADMITTED INTO BELVIDERE FEVER HOSPITAL, GLASGOW, DURING THE RECENT EPIDEMIC, TOGETHER WITH A SHORT HISTORY OF THE DISEASE IN SCOTLAND.

BY WILLIAM DOW, M.B., CH.B. GLASG.,
SENIOR RESIDENT PHYSICIAN TO BELVIDERE FEVER HOSPITAL, GLASGOW.

THE first known cases of this epidemic occurred in Glasgow in March, 1906, but they were associated with cases occurring in the environment of the city within a radius of 15 miles. The first case treated in Belvidere Fever Hospital which was bacteriologically verified was admitted in May, 1906, but there had been a few cases verified in the city in the two months prior to this. From May, 1906, to the beginning of January, 1907, 55 cases subsequently verified were admitted, and these comprised practically all the cases occurring in the city which were sent to hospital. Of these, 2 cases were admitted in May, 5 in June, 7 in July, 7 in August, 5 in September, 14 in October, 5 in November, and 10 in December. Of these, 21 were acute cases (i.e., death taking place within the first 14 days); 2 were mild (i.e., the onset being mild and complete recovery taking place in from 21 to 40 days); 7 were of an abortive type (i.e., those which recovered within the first 10 days); and the remainder (25 in all) ran a chronic course (i.e., the onset being acute but lasting longer than 30 days). These cases were taken almost entirely from the poorer localities in the southern and eastern districts of the city. With the onset of very cold weather in December, 1906, a marked increase took place, so that in January of last year 17 cases were admitted, this being the greatest number since the commencement of the epidemic. 15 cases subsequently verified were admitted in February, 26 in March, 42 in April, and 28 in May, 1907. In all 128 cases subsequently verified were admitted during the first five months of last year. Of these, 55 were acute cases, 8 mild, 9 abortive, and 56 were chronic. During the latter phase of the epidemic the cases have been of a more acute type. The Glasgow epidemic therefore commenced in March, 1906, continued throughout the summer and autumn in a mild degree, and with the sudden onset of very cold weather about the beginning of January of the past year a marked exacerbation took place, culminating in April, and since declining.

The distribution of the cases as regards age, sex, and fatality is given in the accompanying tables. As the cases

The Hunterian Lectures

ON

THE SURGERY OF THE SPINAL CORD AND ITS MEMBRANES.

Delivered before the Royal College of Surgeons of England

By DONALD J. ARMOUR, M.B. Tor., F.R.C.S. Eng.,

HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY; SURGEON TO BELGRAVE HOSPITAL FOR CHILDREN; ASSISTANT SURGEON TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, AND TO THE WEST LONDON HOSPITAL.

LECTURE II.[1]

Delivered on Feb. 26th, 1908.

FRACTURE-DISLOCATION OF THE SPINE.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—In to-day's lecture I propose to deal with the subject of injuries to the vertebral column in so far as they have to do with the main subject-matter of my lectures—viz., the surgery of the spinal cord and its membranes. It will be useful to review briefly the various injuries to which the bones and ligamentous structures surrounding the spinal cord are liable in order to appreciate the nature of the resulting lesion in the spinal cord itself. For this purpose I will follow, with some slight modifications, the classification laid down by Kocher, which I have had placed upon the wall above me.

Classification of Injuries to the Vertebral Column.

I. Partial injuries:
  1. Distortion.
  2. Single dislocation of the lateral joint (dislocation by abduction or rotation of Hueter).
  3. Bilateral dislocation (dislocation by flexion of Koenig).
  4. Isolated fractures of the vertebral column (pressure-fractures).
  5. Isolated fractures of the arches, spinous processes, and transverse processes.

II. Complete dislocation with fractures:
  6. Complete dislocation (dislocation of the lateral joints and displacement in the region of the intervertebral disc).
  7. Dislocations with fractures due to pressure (dislocation of one or both lateral joints and pressure-fracture of the vertebral body).
  8. Complete dislocation with fracture, dislocations with diagonal fractures (dislocation of the lateral joints and dislocation in the region of the fractured vertebræ).

A brief consideration of the various forms of injury and the methods in which the cord is injured is all that time will allow of. In distortion or diastasis limited practically to the cervical region the displacement is slight or wanting. The ligaments are stretched or ruptured by hyperextension or hyperflexion of the column. Symptoms due to cord injury are occasionally seen. The cord is not crushed, but the over-action has been followed by fatal hæmorrhage into the cord (hæmatomyelia). In fact, this form of injury is said to be the commonest cause of hæmatomyelia, occurring, as it does most commonly, in the region of the fifth and sixth cervical vertebræ. In single dislocation of the lateral joint—unilateral dislocation forward—cord symptoms are not commonly present and if present are usually slight. It should be remembered, however, that symptoms pointing to involvement of the spinal cord may appear some time after the injury. Kocher reports a case in which a month's interval elapsed before the cord symptoms appeared. However, the danger of injury to the cord is less in unilateral (i.e., those by abduction and rotation) than in bilateral dislocations. Hæmatomyelia may result also from unilateral dislocation. Though cord symptoms are uncommon those due to injury or pressure upon the nerves passing through the affected intervertebral foramina are common. They consist of radiating pains in the region supplied by the affected nerves. Isolated bilateral dislocations do occur, but practically the intervertebral disc is always ruptured or else the vertebral body is fractured. However, in rare cases so slight has the forward displacement been that the spinal cord has escaped injury. More commonly the lumen of the vertebral canal is narrowed. The spinal cord then suffers any degree of injury between compression and complete rupture. It results from the cord being [illegible] the upper edge of the body of the lower vertebra. The membranes may be partially or completely torn, with extravasation of blood both outside and inside the sheath. It is [illegible] the spinal cord may also be injured by [illegible] as a result of bilateral dislocation. Hæmatomyelia [illegible] associated with the injuries described. [illegible] It would appear that the cord is in greatest danger of injury when the lower cervical vertebræ, the fifth and especially sixth, are the seat of the dislocation, though it may escape even here.

Blasius thus summarises the subject of injury to the spinal cord in dislocations of the vertebræ. In no form of dislocation is injury to the spinal cord a necessary consequence. Such injury is less to be expected in [illegible] and in unilateral dislocation formed of the [illegible] it is always, or almost always, only a slight compression without crushing. In bilateral dislocation [illegible] forward the cord is exposed to more serious injury and seldom escapes entirely uninjured. When the displacement is forward the cord is mechanically affected in most cases, but the cases of severe injury are fewer than those in which all injury is escaped. Finally, the danger is least in bilateral dislocation in opposite directions.

In attempting to reduce a unilateral dislocation by reducing one joint and then the other, as advocated by Hueter, injury to the cord may result. Pressure-fractures occur most frequently at the dorso-lumbar junction. The bodies of one or more vertebræ are compressed, especially in their anterior halves. Fragments may be separated at the upper anterior edge of the body (anterior wedge fragments) or driven back into the vertebral canal (posterior wedge fragments). Occasionally an intervertebral disc may be ruptured without pressure-fracture of the bone. Illustrations of such cases will be thrown on the screen presently. The cord may now and then completely escape injury. When affected the injuries are brought about in various ways. The severest are produced by a posterior wedge fragment dislocated into the vertebral canal, causing more or less extensive contusion of the cord. The lesion may be a total transverse one, or more rarely a unilateral one. It may be accompanied by hæmatomyelia. Root pains, due to pressure upon the nerves in the constricted intervertebral foramina, may be present. Cord symptoms may arise later, due to an insufficient length of time given to treatment, to pressure from callus, or to inflammatory changes in the meninges. Callus is particularly prone to produce pressure symptoms because the fracture heals purely by periosteal bone formation, and so diminishes the vertebral canal space. Isolated fracture of a spinous process may result in injury to the cord by the fracturing force driving the fragment between two vertebræ into the cord. Injury to the cord is more likely to follow upon fracture of an arch, especially when the fragment is completely mobilised.

Complete dislocations with fracture are characterised by an interruption in the continuity of the anterior column formed by the bodies in front, and of the posterior articular column behind. The spinal cord is almost always damaged and often completely destroyed by being carried forward and pressed against the upper edge of the lower vertebra. The liability of the cord to injury is greatest in dislocations with diagonal fractures, in which the dura mater is torn through. The chances of partial injury are more favourable in dislocation pressure-fractures. The cord is carried forward and crushed between the arch of the dislocated vertebra above and the lower fragment of the fractured body below. It is important to remember that the amount of dislocation present at the time of injury may be largely reduced when the fracturing force ceases to act. The necropsy may show an approximately normal vertebral canal with a complete transverse lesion of the spinal cord.

Complete dislocation, with fracture of the upper two cervical vertebræ, is not always immediately fatal, and therefore of practical interest. The relatively large size of the vertebral canal in the cervical region, and especially opposite the upper two vertebræ, accounts for this escape of the spinal cord. A considerable diminution in the size of the canal may occur before pressure symptoms develop. This is in distinct contrast to the dorsal region of the column.

It will thus be seen that the cord may suffer injury [illegible] to compression, contusion, laceration, or complete di
On external examination the cord may
extensive injury it has

---

[1] Lecture I. was published in THE LANCET of March 7th, 1908, p. 693.

in the latter part of the epidemic. It has, as a rule, occurred on the first or second day but sometimes as late as the second week. Its most common situation has been the angles of the mouth, as in a pneumonia, but frequently it has appeared on the cheek, around the ears, and the alæ of the nose. The number of the clusters of herpetic eruptions has varied from six to eight. In two instances the cluster upon the side of the face and neck has been as large as, or larger than, the hand. In one case the herpes has appeared extensively over one shoulder blade, and in another over the inside of one knee. In one instance a scarlatiniform rash has been present soon after the onset.

In two of the chronic cases an eruption beginning as papules and becoming pustular appeared distributed over the body. It ran a moderately definite course and but for the fact of its healing did not differ a great deal in appearance from those generally distributed septic infections of the skin frequently seen in emaciated children. The rose spots described by other writers have never been observed in this epidemic.

Nervous system.—Variation in the nervous symptoms naturally occurs according to the extent and intensity of the meningitis and the degree in which the cerebro-spinal axis is congested or implicated, but certain symptoms have occurred in all, or nearly all, cases and must be considered characteristic. Pain, already described as an initial symptom, has continued during the acute period of the illness. It has ordinarily been severe but its intensity has varied in different patients. Its most frequent seat has been the occiput, the frontal region, and the top of the head, and the same patient at different times has complained of all of these parts. It has also been common in the nucha and along the spine. The epigastrium, the umbilical and lumbar regions, and the extremities are frequently affected, and the pain shifts from one part to another. It has been more common and persistent in the head and along the spine than elsewhere. In these situations its appearance is in all cases coincident with the onset of the disease, and it begins to abate as a rule within the first few days and is much less pronounced by the end of the second week. The state of the mind is that of apathy or indifference, and between this mental state and coma there is every grade of disturbance. Delirium has not been infrequent. It is rarely quiet in form and seems chiefly the result of pain which rouses the patient from the state of stupor and causes him to cry out frequently and name the affected part. If the pain is severe such patients can hardly be restrained in bed, their restlessness is extreme, and their management is difficult. The patient may be quiet for a few minutes, and then aroused roll and toss from one part of the bed to another. It has always been primary, occurring with the onset of the disease, and has lasted a variable time, in some cases passing off after a few days and in others persisting until death. When delirium ceased it was an indication that the case was passing into a chronic form and did not necessarily mean commencing recovery. The form has varied from muttering to maniacal delirium, but in most cases the condition suggested that the origin of the mental symptoms was rather to be sought in the action of pain on a semi-conscious subject rather than in cerebral intoxication seen in other forms of infective disease. In one instance insanity was diagnosed at the onset. The patient was suffering from a muttering form of delirium. He seemed to answer certain questions quite intelligently, but talked away to himself in an incoherent rambling manner. There was no complaint of pain. The fluid removed from the spine was purulent and he died after an illness of six days' duration.

Hyperæsthesia of the skin has been a common symptom, friction upon the surface and even slight pressure with the fingers eliciting cries of pain. Contraction of certain muscles has been present in all cases, unless sometimes in very young children. This contraction has been most marked in the posterior muscles of the neck causing retraction of the head, but it has been also common in the posterior muscles of the trunk causing opisthotonos, and in less degree in those of the abdomen, and in the hamstring muscles of the lower extremities. In consequence of this the patient lies usually with his head thrown back, with the thighs and legs flexed, and with some degree of arching of the spine. Contractions have also occurred in the flexors of hands and feet, especially affecting the thumb and great toe. The varieties of these symptoms are naturally best seen in the chronic cases. In those which end fatally the muscular contraction and rigidity continue to the end, and in some of these the body is so rigid that it can be lifted like a statue. However, during the intervals of apyrexia which often occur in these cases the muscular rigidity frequently passes partly off, and in rare instances completely to reappear again with the recrudescence of the fever.

The plantar reflex has been exaggerated in acute cases before the onset of coma. It has been present throughout the disease in all cases, but in the chronic it is somewhat less active. Babinski's sign has never been obtained in any of the cases. The other superficial reflexes have also been active in the early stage but have been difficult to obtain later in the disease. The knee-jerk is generally exaggerated in acute cases before the onset of coma but may be unequally present in both limbs. It is almost generally absent throughout the course of the disease in all the chronic cases. The loss of knee-jerk persists into convalescence. Ankle or patellar clonus has never been elicited at any stage of the disease, nor has increased reflex of the tendons of the arms and wrists been observed.

Rapidly progressing emaciation begins to be observed in chronic cases from the fourteenth day onwards. The skin, particularly of the abdomen, in these cases becomes dry, wrinkled, and inelastic. The muscles also become extremely atrophied. Trophic lesions of the skin have not been observed. In cases which recover flesh is put on rapidly.

Chronic hydrocephalus is fairly common and its presence may be recognised from the twentieth day onwards and sometimes earlier. The condition is suggested by the extremely wasted appearance of the face and its small size in comparison with that of the head. The eyes have a fixed stare. There is commonly retraction of the upper eyelid, which is occasionally associated with an irregular form of nystagmus, and rhythmic contraction and dilatation of the pupil, a form of hippus which is described fully later. Optic neuritis is found in all these cases. Headache already described is present. The mental condition is variable. The mental faculties in some degree as a rule are retained, but sometimes there is coma. Convulsions occasionally occur in children at this stage. Polyuria is also a symptom. In these cases, although the symptoms present for the most part can be referred to the hydrocephalus, it is noteworthy that the organism is still usually abundant in the spinal fluid. The extreme loss of nutrition is not due to the loss of power of feeding or digestion, as such patients in general feed well. Paralysis of any muscle or group of muscles has only occurred in one case, when complete hemiplegia affecting the right side developed a few days before death. In the very acute cases, however, difficulties of deglutition appeared shortly before death.

History of convulsions is commonly obtained as accompanying the onset in children under a year, but no such history has been recorded in adults. Convulsions have occurred in the course of the disease in children in acute cases, and they have been found associated post mortem with leptomeningitis extending over the vertex of the brain. They also occur in children throughout the course of the disease in chronic cases, when basal meningitis is present. Convulsions have been absent in adults but seem to have been represented by muscular twitchings in acute cases. These twitchings have been observed in the face, the arms, and the legs. They occur only at intervals and are commonly produced reflexly by movements of the limbs or by touching the skin.

Organs of special sense.—Of the organs of special sense the eye and the ear have been most frequently affected. With regard to the former, the pupils in the irritative stage of the disease have been contracted when there has been delirium. In the stage of coma they have commonly been dilated. Inequality of the pupils has been very frequent in all stages of the disease. They have commonly responded very feebly to light. An irregular form of hippus has been frequently observed both in acute and in chronic cases. In this the pupils have contracted and dilated with something approaching a rhythmic frequency, the oscillations commonly occurring from 10 to 15 times a minute. A comparison between the maximum of dilatation and maximum of contraction has been greater than normal and the oscillations have been irregular in speed and in rhythm. This has occurred without the eye being illuminated or the gaze being fixed on a distant object. Strabismus has been moderately common at all stages, being apparently due to pressure rather than to central lesion of the nerve, as it varied in the same subject from day to day. In only one case which recovered was the squint permanent, and in this case it was internal.

In the first case the ends of the cord were three-fourths of an inch apart (two centimetres). Working upon the subject of regeneration Marinesco and Minea have described the appearances found in the cords of dogs examined at periods varying from 1 to 15 weeks after section, and also in two cases of compression of the spinal cord in man. The conditions found were very similar in both the experimental and the pathological conditions. New formation of nerve fibres occurred, as described both by the authors and by Cajal, in peripheral nerves—namely, progressive growth of old fibres, and multiplication by successive dicrotomy of fibres of new formation. Growth occurred from both upper and lower ends, but seemed to be more prolific from the posterior roots upwards than from above downwards. The new fibres were of varying calibre. Some were myelinated, but most were not. They ended in cones of growth of spherical terminal masses and frequently had fusiform swellings in their course. Cells which are termed "apotrophics" played a somewhat important rôle here, as they do in peripheral nerve regeneration. These are fusiform cells, which were found in the tissue between the divided ends a few days after section, with a fusiform nucleus, and rich in chromatin granules. Sometimes they were elongated, with several nuclei, and were described as protoplasmic bands. They had chemiotaxic properties, by which the young axons were attracted, often actually drawn into their interior and nourished. The new nerve fibres extended by growing along these bands of apotrophic cells, and also by following the lines of the new vessels forming a sort of perivascular reticulum. The course of the fibres was very irregular. Many actually doubled back on themselves and few succeeded in crossing the cicatrix, so that in spite of the apparent double cord and root regeneration there was no functional regeneration. In order to accomplish this it would be necessary for the proper neurons to become connected up as before, an event which, in the opinion of these investigators, can only occur, if at all, with extreme rarity.

Fickler, experimenting upon the changes found in the spinal cord after contusions of various degrees, reports finding evidences of regeneration. This occurred only in the nerve fibres, never in the ganglion cells. If the ganglion cells controlling the nerve fibres were destroyed by pressure or by any other cause regeneration did not occur. The commonest source from which regeneration proceeded was the spinal ganglion nearest to the focal lesion. His experiments seem to indicate that regeneration only occurs in sensory fibres from the spinal ganglia and in the fibres uniting various segments of the spinal cord. Consequently, the number of fibres capable of regeneration is not very large. When these regenerated fibres reached the grey substance they travelled upward for a considerable distance and even came into relation with the dendritic processes of the ganglion cells of the grey substance. According to Fickler the fibres of Clarke's column do not appear to be capable of reaching the central neurons. He concludes that the functional result attained by such regeneration is probably insignificant.

Pierce Clark, after a searching analysis of all the facts, submits the following as conclusions in answer to the query as to whether the tracts of the nervous system regenerate. 1. Animal experiments fail to provide conclusive data that central tracts of the nervous system ever regenerate, so that the former function is restored. ... In warm-blooded animals, and in the human species in particular, an abortive attempt on the part of the cord to regenerate is largely, if not solely, confined to fibres of undoubted peripheral type. 2. Histological analysis of cases of hemi-section, compression paraplegia and myelitis, and similar destructive lesions of the cord, fails to show positive evidence that actual structural regeneration of axis cylinders ever occurs in the central nerve tracts of the human spinal cord. In a case of complete division of the brain and spinal tracts there is simple degeneration, followed by sclerosis. 3. A most acceptable reason for non-regeneration of such tracts is shown in that the compressed nerve fibres do not possess a neurilemma sheath from which the nerve regeneration mainly, if not solely, occurs. This lack in cord and brain tracts, in contrast to the regenerating peripheral nerves, is due possibly to a difference of embryological origin of these two structures of the nervous system.

Dr. Gordon M. Holmes, director of the research laboratories at the National Hospital for the Paralysed and Epileptic, has kindly placed at my disposal the results of his researches on the subject. He says:—"The evidence against the opinion that regeneration of completely interrupted fibres of the *central* nervous system may occur is threefold: 1. There are no satisfactory or conclusive observations that *central* fibres do regenerate. 2. When a central tract degenerates its place is soon occupied by such dense sclerotic tissue that it is scarcely credible that such delicate structures as regenerating axis cylinders should be able to find their way through it. On the other hand, such cells as the proliferated neurilemmal elements of a secondarily degenerated peripheral neuron, which it is generally assumed possess a chemiotactic attraction for the regenerating axis cylinder, do not exist in the central nervous system. 3. There is definite evidence, for a considerable number of systems at least, that when a central fibre is interrupted its cell of origin soon undergoes complete atrophy and disappears."

The clinical evidence, when analysed, in support of regeneration occurring in the spinal cord is even less convincing than the experimental. That recovery of function after total loss does occur may be explained in several ways. This loss may be due to pressure or œdema, producing physiological abrogation of function without necessarily destroying the nerve elements completely. On removal of the compression the fibres recover their powers of conductivity. Or the function of fibres actually destroyed may be taken over by other fibres which have escaped. This would appear to take place in relation to the bladder and rectum in cases of hemisection of the spinal cord.

The question of operation.—Paulus Ægineta in the seventh century was the first to advise operation for fracture of the spine. He says (Book VI., Sydenham Society's Translation): "The round bodies of the vertebræ may sometimes be crushed, in which case the membranes of the spinal marrow, or the marrow itself, being compressed, sympathetic nervous affections take place, and death speedily follows, more particularly if the vertebræ of the neck be affected. Wherefore, first having given warning of the danger, we must if possible attempt to extract by incision the compressing bone, or if not we must soothe the part by anti-inflammatory treatment. But if any of the processes of the vertebræ, of which the spine, as it is called, consists, be broken off, which will readily be felt upon examination by the finger, the broken piece yielding, and returning again to its position, we must make an incision in the skin externally, and extract it, and having united the wound with sutures, pursue the medicaments for healing wounds." But the subject did not receive serious attention until Paré in the eighteenth century recommended operative treatment. Heister recommended extraction of the fragments in cases of fracture where the depressed fragments compressed the cord. "But to offer the patient no assistance because we despair would seem cruel and uncharitable, therefore we must try our skill though our attempts should be in vain; in order to which the surgeon must lay bare the fractured vertebræ with a scalpel, and replace or else remove such fragments as injured the spinal marrow." The first operation for fracture of the spine was performed by Louis in 1762, though one of the earliest of the more formal operations was carried out in 1814 by the younger Cline. In 1823 Sir Astley Cooper wrote: "If you can save one life in ten—nay, one in a hundred—by such an operation, it is your duty to attempt it, and he who says it should not be attempted is a blockhead."

The questions that will arise in discussing the subject of operation in cases of fracture-dislocation of the spine are, in order of importance: 1. Will any benefit to the patient result from the operation? 2. Will his life be endangered by the operation? 3. Will he be made worse as a result of the operation?

Let us take these in the reverse order. The condition will certainly not be aggravated as a result of the operation. This statement is made with the proviso that the operation is undertaken by a competent surgeon, accustomed to operate frequently upon the spinal cord, and whose aseptic technique is beyond reproach. Unless the operator has had considerable experience in spinal surgery it is very easy to overlook the cause of compression. It is essential, in order that an operation should be perfectly successful: (1) to remove enough laminæ to be absolutely sure that there is no remaining pressure on the cord; (2) to remove any projecting bone, whether it be a portion of the vertebral bodies, or one or more articular processes; (3) to remove all blood-clots, even though laminæ of unaffected vertebræ have to be removed to do so; (4) to open the dura mater to ascertain definitely the condition of the cord; and (5) to see that the cord dilates to been found to be enlarged. The bowels, as a rule, have been constipated. There has been loss of control of the rectum in all the acute cases and also in many of the children even when they have been conscious.

Urinary system.—In the acute stage of the illness the amount of urine passed has not been altered. In chronic cases, however, where hydrocephalus has developed, the amount has been greatly increased and the colour has been pale. No sugar has been present in any of the cases. Albumin has only been found very occasionally and in small quantity in acute cases shortly after onset. It has never been present at any other stage of the disease. Blood has never been found. There has been no instance of nephritis observed. Incontinence of urine has been common in children throughout the course of the disease. It has only been observed in adults during the state of unconsciousness.

Joints.—Arthritic pain, though it has been a feature of some other epidemics, has only occurred in a very few cases. The wrists, knees, and ankles have been chiefly affected. The joints have been tender to touch. This symptom when present appeared shortly after the onset and subsided in a few days. A purulent arthritis has occured in only two cases. In the first case the knee-joint alone was affected. The patient had a sharp attack of the disease, which aborted. The swelling appeared the day in which the crisis occurred, when the patient was otherwise well. The cavity of the joint was much distended. The skin was red and tender to the touch. On exploring thick yellow pus was obtained, from which the diplococcus of Weichselbaum was isolated in pure culture. The knee was opened and drained and the patient made an uninterrupted recovery with, however, an ankylosed joint. The other case was chronic in character. Swelling of both wrists, both ankles, and the right knee-joint developed within a few days of each other well on in the course of the disease. Slightly turbid fluid was obtained on aspirating the knee-joint and the diplococcus of Weichselbaum was again isolated in pure culture from this fluid. This patient died eventually, but the swelling of the joints subsided without surgical interference.

Historical Note.

In view of the fact that cerebro-spinal fever has assumed epidemic proportions in Scotland for the first time, an account of its history and its clinical aspect should not be without interest.

The first case definitely recognised occurring in Scotland was communicated to the Glasgow Clinical and Pathological Society in 1883[1] by the late Dr. James Finlayson. This case was admitted to the Glasgow Western Infirmary in February of the same year and was verified by post-mortem examination. However, in 1878 the late Dr. T. J. Maclagan had reported in THE LANCET[2] a series of cases occurring in Dundee, but doubt was expressed at the time as to their real nature, many considering that they were aberrant cases of typhus fever, and a careful comparison of his clinical account with the symptoms observed in this epidemic leads to the belief that such was really the case. One of his chief points, the absence of rash, is of much less weight at the present time, as it is now known that the characteristic rash of typhus fever is absent in fully a third of the cases. Dr. Maclagan reported these cases again more fully in the *Edinburgh Medical Journal* in the year 1886.

In May, 1883,[3] a case subsequently verified by post-mortem examination was admitted to the late Sir William Gairdner's wards in the Glasgow Western Infirmary. In January, February, and March, 1884,[4] the first definitely recognised outbreak of this disease in Scotland occurred in Galston, Ayrshire. These cases, six in all, were reported by Dr. William Frew (Kilmarnock) to the Clinical and Pathological Society of Glasgow in May of that year. Two of them were verified by post-mortem examination. Dr. Frew also describes some cases of an abortive type which occurred at the same time. Immediately on seeing this paper Dr. Byrom Bramwell[5] wrote to Dr. Frew stating that he himself had observed sporadic cases in Edinburgh. Dr. Alexander Collie[6] also wrote about the same time stating that cases of this disease had come under his own observation in Scotland.

In 1885[7] the late Dr. Finlayson reported a further case occurring in his wards in which the diagnosis was confirmed post mortem. In the same year[8] Dr. J. Nigel Stark reported two cases occurring in the Royal Infirmary, Glasgow, in which the diagnosis was likewise confirmed post mortem. In 1887[9] Dr. Anstruther Davidson (Sanquhar) reported a case which recovered, convalescence being very protracted. From 1884 to 1888[10] single sporadic cases of the disease occurred in Rothesay, Dumbarton, and Kilmarnock, while in the four years six further cases were observed in Galston. These were also recorded by Dr. Frew. In some of these the diagnosis was verified by pathological examination. In 1892[11] Dr. W. A. Maclachlan of Dumbarton reported a case which recovered. At the annual meeting of the British Medical Association at Carlisle in 1896 Dr. Frew read a further paper in which he states that he had collected notes of upwards of 100 cases of cerebro-spinal fever which had occurred in Scotland without, however, specifying the exact localities in which they occurred. A third fatal case verified post mortem was admitted into the wards of the late Dr. Finlayson in 1900. In the same year[12] Dr. T. K. Munro reported a case occurring in the *Glasgow Royal* Infirmary in which recovery took place in five days. The three cases of Dr. Finlayson, the case of Sir William Gairdner, and the two cases of Dr. Stark all occurred in persons residing in Glasgow and afford proof that the disease has been present in the city since 1883.

Professor J. Glaister made in 1902 a post-mortem examination on a case of sudden death occurring in Paisley. In his report to the corporation he stated that he had found the characteristic organism of cerebro-spinal fever in the exudation round the brain and spinal cord, and he also expressed the opinion that six other cases occurring at the same time were clinically cases of the same disease. Six undoubted cases occurred in Rothesay between May 6th, 1904, and June 4th, 1905, one of which was verified by lumbar puncture. Dr. F. Dittmar made a report on these to the Local Government Board of Scotland. Dr. J. Wallace Anderson has believed for a considerable number of years that the disease was constantly present in Glasgow in small amount. He has published a note of his cases in the Transactions of the Epidemiological Society and he recently gave a demonstration of cases that had recovered in the Glasgow Public Health Office. I had the fortune to be present at this demonstration and I had no doubt that the majority of his cases had been genuine examples of the disease. Sporadic cases have therefore occurred in Scotland during the last 20 to 30 years, but this is the first occasion there has been an epidemic comparable in extent with any that has occurred in the Continent or America.

Belvidere Fever Hospital, Glasgow.

A REMARKABLE CASE OF PERSISTENT INGESTION OF NEEDLES

AND THEIR REMOVAL FROM DIFFERENT PARTS OF THE BODY, ESPECIALLY FROM THE ORGANS OF THE ABDOMINAL CAVITY, BY LAPAROTOMY SEVERAL TIMES REPEATED.

By ALEXANDER NICOLL, M.D.,

ASSISTANT PROFESSOR OF SURGERY, FORDHAM UNIVERSITY MEDICAL COLLEGE, NEW YORK; VISITING SURGEON TO FORDHAM HOSPITAL; AND CHIEF OF THE SURGICAL CLINIC, ST. VINCENT'S HOSPITAL, NEW YORK.

OPERATIONS for the removal of needles from the human body are by no means infrequent, but a somewhat extended examination of surgical literature has not discovered a case in which the patient so persistently ingested needles and submitted to severe operations for their removal as the one narrated in this paper. It has attracted considerable attention through her readiness to give information when she was out of the hospital, and now that the end has come it seems fitting to publish the details, if it serve no other purpose than to add a very unique case to the already varied collection of records of foreign body perforations of the gastro-intestinal tract.

On Oct. 26th, 1906, the patient who is the subject of this are so few any elaborate discussion of these figures is unnecessary. Certain points may be noted: the number of males and females has been practically identical. The fatality during both phases of the epidemic has been practically the same—viz., about 73 per cent.

The clinical symptoms of the cases in Belvidere Fever Hospital, as they have been observed during the recent epidemic, are recorded below under appropriate headings.

Symptoms of onset.—The onset has in general been sudden. Headache and vomiting have been the chief initial symptoms. The former has always been present and the latter has only been absent very occasionally. In adults there has often been a history of shivering or rigor and in infants of convulsions. Vertigo has been present in many instances at this stage, sometimes so acute as to cause the patient to fall down on the street. Prodromal symptoms have generally been absent, but as the great majority of the cases were children their frequency cannot be estimated. Malaise has been occasionally present for a few days prior to the onset, and in some cases a feeling of uneasiness incapable of definition has preceded the acute attack by a number of hours. Sore-throat of one to two days' duration has been noted. Nasal discharge has been only occasionally observed. The onset has in many cases been fulminant, in some instances the patient having taken a full and hearty meal immediately before.

The physiognomy has been very characteristic. Generally the cheeks are flushed and in acute cases the flush is dusky or even cyanotic. Herpes when present usually appears round the lips at this stage, so that the facies resembles that of a typical pneumonia. There is generally a look of anxiety. In severe cases the conjunctivæ are suffused. The condition of the pupil is variable and will be discussed more fully later. A petechial rash sometimes appears within the first 12 hours in fulminant cases, but when present in other cases it has commonly been observed for the first time on the second, third, or fourth day. The patient is restless and lies with his head rigid or somewhat pulled back, and the arms and legs may be tossed from one part of the bed to another. There has always been stiffness of the head and neck, unless sometimes in children under a year old, when even this sign has been absent. Kernig's sign has been present in the majority of the cases a few hours after the onset, but by no means always. A type of case has occasionally occurred, death taking place in from 24 to 48 hours, in which neither rigidity of the head and neck nor Kernig's sign has developed. All degrees of mental activity have been displayed, but stupor more or less profound, and less frequently delirium, have succeeded the onset according to the gravity of the case.

The type of case has varied considerably, and for purposes of description they will be referred to hereafter under the following heads: the acute, the chronic, the mild, and the abortive. In the acute case delirium with more or less coma develops within the first few hours, and death occurs within the first 14 days. The chronic case is generally acute at onset, being ushered in with delirium, semi-coma, or coma, within the first few hours, but a fatal result does not immediately occur, and after about 14 days the case assumes a chronic character. Mild cases are those in which the symptoms of onset are quite characteristic, but there is an entire absence of delirium and coma; consciousness persists throughout the attack, and there is only moderate complaint of pain. In some of these cases there is considerable retraction of head and neck, and even opisthotonos. Abortive cases are those in which the onset has been commonly acute, and in rare instances mild, but in which recovery is complete within the first few days.

Skin.—The features have as a rule been flushed at the commencement of the disease, but in advanced cases they have been pallid. Temporary flushings of the face and of the skin generally have been common throughout the course of the disease. On the face especially circumscribed areas of deep congestion surrounded by areas of pallor have been seen. These are very evanescent, passing within half an hour from the stage of extreme brilliance to a condition only recognisable with difficulty. Goose skin has been common in the chronic stage. The tache cérébrale has been common throughout the course of the disease. Considering that the disease has been named from the eruption which accompanies it, it is noteworthy how seldom the true rash has been present. This rash, however, does not conform in the least to any of the types which we are accustomed to associate with the acute exanthemata. It has consisted of small hæmorrhages into the more superficial part of the corium, which on appearance have been bright purple in colour and of irregular form. They commonly have varied in size from ⅛ to ¼ inch in diameter, but smaller and larger elements have been not unusual. The largest observed approached the area covered by a shilling piece. The common duration of these hæmorrhages has been from three to four days and they have faded in brightness usually within 24 hours. They pass through the ordinary stages of the disappearance of a hæmorrhage. Their whole course is much shorter than that seen in the typhus eruption and they have never been preceded by the roseola commonly present in the latter disease. When these hæmorrhages have occurred in the subcutaneous tissues they have been faint blue in appearance. Another feature of the skin occasionally observed has been a mottling not unlike that seen in typhus fever, but this has never appeared with the widespread distribution common in the latter disease. This has been observed in seven cases, and in the first week of the disease. It has only been associated with the rash in one case. As regards the appearance of the eruption there is little to distinguish it from an ordinary purpura except its rapid evanescence. This would seem to show that the amount of blood effused is very small and very superficial. This eruption has commonly appeared from the first to the fifth day, the commonest days having been the third and fourth. A petechial eruption not distinguishable from that described distributed generally has been observed in four instances immediately prior to death. In cases which have developed chronic hydrocephalus an eruption of very small petechiæ distributed more or less generally have been common shortly before death. These have been a faint blue in colour and not easily visible. Six cases out of 55 treated during 1906, or 10·9 per cent., had a generalised petechial eruption all over the body. 27 out of 128 cases, or 21·09 per cent., treated during the first five months of 1907 had generalised petechial eruptions, so the petechiæ have been much more common during the latter phase of the epidemic. Four out of these latter cases had hæmorrhages also under the conjunctivæ. Two had hæmorrhages under the conjunctivæ alone. Recovery has only taken place in one case where petechiæ were found in the skin. In this case the fever continued for 160 days, recovery taking place with deafness.

Herpes has occurred in 18·1 per cent. of cases in the first phase of the epidemic and in 21·09 per cent. of cases in the second phase. The frequency of the occurrence of herpes and the petechial rash has been therefore exactly the same abdomen three needles were discovered, two of them lying in the parietal peritoneum and one in the preperitoneal areolar tissue. All seven needles were removed, those lying in the peritoneum requiring for their removal a simple incision of that membrane, the resulting wounds being closed by individual running sutures of No. 1 catgut. The single needle which lay in the preperitoneal tissue was reached by freeing the peritoneum from the deep fascia and was thus removed extra-peritoneally. Further search showed the presence of a needle in the cul-de-sac of Douglas. This was apparently safely encysted, had caused no pain, and required for its removal a marked extension of the incision with a much greater tendency to post-operative accident, and the prolongation of an already necessarily protracted operation. It seemed wise to leave it where it was being so well protected. The small intestine was next investigated by gently passing it between the fingers its entire length. It was found to contain no needles nor any other unusual foreign bodies, and at no point was there any scar to show a possible previous perforation by any of the needles found elsewhere in the abdominal cavity. All the remaining abdominal viscera were palpated, as also were the walls of the peritoneal cavity. Nothing else of an abnormal nature was found. I closed the abdomen by layer sutures, plain catgut No. 2 being used throughout; skin edges were approximated by a subcuticular suture of the same material.

One event in an otherwise uneventful recovery deserves mention and is of interest in the light of later knowledge. 24 hours after operation the patient, who had been progressing exceedingly well, utterly collapsed and responded to vigorous stimulation only after an hour of hard work with high saline enemata with whisky, hypodermatic injections of the usual heart stimulants, and intravenous infusion of normal salt solution. I am indebted to Dr. William Hinz, then house surgeon of Fordham Hospital, for his efficient aid at this time. After this temporary set-back the recovery of the patient was rapid and satisfactory. On the third day after operation she began taking soft food. On the fourth day her bowels were moved thoroughly by fractional doses of calomel followed by salts. On the fifth day temperature and pulse were normal and she was allowed a restricted solid diet. On the tenth day her wound was dressed and found healed. She had not vomited since the operation. Excepting the fact that she was occasionally nauseated and complained of some abdominal pain her convalescence was uneventful.

When confronted with the conditions found at the operation the patient became taciturn and unresponsive and it was not until six months later, when her hysterical condition had temporarily disappeared, that she confessed to having "eaten" the needles about 18 months before she came under observation and said that she had swallowed them all at the same time. How many she had taken she was unable to state.

In the foregoing description of the operation the use of the word "needle" requires, perhaps, some explanation. In not every instance was a complete needle encountered but each piece was of sufficient length to warrant the assumption that it represented a full needle. They varied in length from half an inch to the full three-inch length. Sometimes the point was lacking, sometimes the eye; in every case the metal was much corroded and in some cases so friable as readily to break up into several pieces when grasped between the thumb and fingers. So firm was the clutch of the enveloping tissue upon these roughened bodies that no needle could be *pulled* out, but each required to be *cut* out.

The remarkable versatility of the great omentum was beautifully demonstrated in this exploration. Needles just in the act of perforating the stomach or intestinal walls were invariably covered by a small portion of omental tissue. Those which had entirely perforated were found in the omentum itself, and the course of those lying in the abdominal wall was indicated by the needles found in the omentum at various levels. Apparently the omentum anticipated the perforation, enshrouded the offending body in its protecting folds, and passed it on to the comparative safety of the abdominal wall. The fact that the needles which escaped from the stomach into the duodenum should traverse safely the entire length of the small intestine and then find the lumen of the colon too cramped to allow of their continued progress is but another illustration of the well-known paradox. The needle found in the cul-de-sac of Douglas probably perforated the upper part of the rectum itself. However, that the small intestine is but human after all was shown later on in this case.

On Nov. 30th, three weeks after operation, the patient again required attention. In the afternoon of that day she complained of nausea, faintness, and abdominal pain. This pain she significantly described as of a sticking character and localised at a point one and a half inches above the umbilicus and slightly to the right of the median line. The pain and nausea continued and increased, the epigastrium became tender, the temperature rose to 101°, and the pulse quickened to 120 per minute. At 7 o'clock the patient vomited four ounces of pure, bright-red blood. Suspecting another perforation I deemed operation advisable.

At 12 o'clock, under ether anæsthesia, I opened the abdomen through the upper portion of the left rectus. The large and small intestines were normal save for the scars already mentioned. A good-sized hæmatoma was discovered between the layers of the omentum, and the formation of this accounts, I believe, for the severe secondary shock which has been described as occurring 24 hours after the first operation. The clotted blood was merely shelled out and the cavity allowed to take care of itself. At the site of the perforation of the first needle removed at the first operation there was some thickening, suggesting the presence of a gastric ulcer. The stomach was opened at this point, its cavity thoroughly explored, and nothing found. The only explanation of the hæmatemesis seemed to lie in bleeding from minute ulceration at the site of the scar or from an inaccessible lesion of the œsophagus. The thickened portion of the stomach wall was turned in by means of four or five interrupted stitches of black silk. The abdomen was closed by layer sutures in the usual manner. No drainage was employed. The patient again made an uneventful recovery.

On Dec. 15th, after the patient had apparently recovered and had been up and about the ward for several days, she again vomited about three ounces of blood unmixed with food and bright red in colour. She was put to bed and all food and all medication by the mouth were stopped. There was no particular abdominal tenderness. She was occasionally nauseated during the next 24 hours, but improved and was up and about at the end of three days.

Jan. 1st, 1907, was the starting point of another attack similar to the one just described and for several days she was again confined to bed. Repose and complete stoppage of food again proved sufficient curative measures.

On Jan. 10th a point of local tenderness appeared about two inches above the umbilicus and evidences of deep-seated inflammation were discovered. The patient was put to bed and an ice-bag relieved the pain. On the 12th the point of an ordinary sewing needle presented itself at the centre of the inflammatory mass and was removed. Occurrences similar to this, at times previous to her submitting to treatment, account, I believe, for the presence of the irregular abdominal scars about which she was so reticent. The small wound in the skin immediately healed but the pain continued. Vomiting again occurred and persisted but the vomitus was not discoloured with blood. The upper central portion of the abdomen became distended and tender, the temperature rose, and, in short, the patient exhibited all the signs of obstruction of the small intestine. Though the bowels were moved freely with enemata the obstructive symptoms persisted.

On Jan. 15th an operation was resorted to for the third time. The abdominal cavity was opened above the umbilicus in the median line. The point of obstruction was found in the small intestine about 24 inches from the beginning of the jejunum. The lumen of the bowel was almost obliterated by dense scar tissue in the intestinal wall and the obstruction was completed by encircling bands of omental adhesions. In this mass of adhesions and lying immediately next to the bowel itself was a cambric sewing needle. Just above the obstruction another needle was discovered in the act of perforating the intestinal wall. Both needles were removed and were found to be entirely intact and bright and shining. They had none of the corroded, "digested" appearance of the needles removed at the first operation. After removing the needles and freeing the bowel of the constricting bands, I split the intestinal coats through the stenosed area for a distance of about two inches and sewed the resulting wound transversely with a through-and-through running stitch of black silk. A single layer of Lembert stitching covered this suture line. The abdomen was closed with layer sutures without drainage. Again the patient made a good recovery and was out of bed on the fourteenth day. She remained under observation for about six weeks, during

Nystagmus, both horizontal and vertical, has been commonly observed in very acute cases and occasionally in the chronic stage.

A curious condition, consisting of an associated movement of the upper eyelids, pupils, and eyeballs, has been occasionally observed in chronic cases in the stage of chronic hydrocephalus. This consisted of spasmodic retraction of the upper eyelids, accompanied with the form of hippus already described and with an irregular form of nystagmus, but not true nystagmus, where an involuntary oscillation of the eyeball occurs from side to side of the central line of vision. In these cases the nystagmus has consisted in irregular twitchings of the eyeballs in all directions and not from side to side of the middle line. Retraction of the upper eyelids has been moderately common in the stage of chronic hydrocephalus. Ptosis has not been observed. Conjunctival hæmorrhages have been only observed in six cases. In acute cases there has commonly been a uniform diffuse redness of the conjunctivæ. In only a very few cases has there been purulent conjunctivitis and this in exceptional instances has proceeded to ulceration of the cornea. Out of a series of about 40 cases which were examined carefully for changes in the fundus optic neuritis has been observed in all the cases which had developed chronic hydrocephalus, but has not been found at any other stage of the disease. In the acute cases hyperæmia of the optic discs has commonly been noted. A few patients have appeared to be blind throughout the course of the disease but none of these have recovered with blindness.

As to the ear, both the middle ear and the central auditory system have been frequently affected. In children, inflammation of the middle ear with purulent discharge has been moderately common. The diplococcus of Weichselbaum has never been isolated in pure culture from this discharge. Out of the 14 recoveries in the first portion of the epidemic complete deafness was present in four. In two of these the disease was abortive in character and in two it was chronic, and the deafness was observed in all immediately after the initial stage of coma had passed away. Out of 30 patients who recovered from January to May, 1907, five were completely deaf. Of these, three were abortive cases and two were chronic, and the deafness was observed in all, in the early stage of the disease, as soon as the stupor had passed away. Other patients, especially children in whom a fatal result occurred, may have been deaf during the course of the disease, but it has been difficult to make this out. The deafness in all cases has been bilateral and complete. In none of these cases has improvement in hearing taken place since dismissal. No discharge from the middle ear has occurred in any of those who recovered with deafness.

Taste and smell have not been affected.

Nasal discharge has not been a feature of any of the cases.

Temperature.—At the onset in acute cases the temperature commonly ranges from 102° to 104° F. In these cases it commonly continues at this level without remitting throughout the course of the illness and rises or falls immediately before death. In many cases, however, in which coma has occurred within the first few hours after the onset the temperature has been sub-febrile, normal, or subnormal when admitted on the first or second day of illness. Fever has probably been present at the onset and the temperature has fallen with the commencement of coma. When the acute case aborts the temperature remains high for some days and falls by crisis or less commonly by lysis. In the chronic cases there has been so much variability in the course of the temperature that classification is impossible. In many of these cases the temperature has been apparently arbitrary. In some there have been periods of apyrexia, lasting from three to seven days, followed by febrile periods remittent in character, lasting for about a similar period, though the periods of apyrexia became gradually longer as the illness progressed. In one chronic case this form of fever lasted for 160 days, but the pyrexia did not occur at regular intervals. In this case during the latent intervals of the fever all the symptoms of pain, rigidity, &c., passed completely away, but the renewal of the fever on every occasion was accompanied with nausea and vomiting, headache, and rigidity of the muscles. There is, however, one form which has been much more common than the rest. In this commencing at a period from the eighth to the fourteenth day the temperature has taken on a markedly remittent type, the daily swings amounting to as much as 3° or 4°. The maxima and minima do not regularly occur at set hours, and consequently the phenomenon is much more discernible in a four-hourly chart. This remission in some cases reaches the normal line, or even a degree below it, and persists for a considerable time. There is no phenomenon such as sweatings or burnings of the skin associated with this daily oscillation, but headache and vomiting are common. The oscillation may persist for five weeks or longer, and either end abruptly or by the excursus becoming gradually less marked. The return of the temperature to normal may either mean approaching convalescence or the approach of a stage of gradual wasting, fatal sooner or later. The commencement of this stage of daily remission supervenes sometimes on the acute high fever, while sometimes there is a period of several days' normal temperature between the end of the primary fever and the beginning of this stage. In many of the chronic cases the temperature has been more or less normal for weeks before death. In some of the milder cases the temperature has remitted regularly from 101° to 102° to normal in the morning throughout. In cases of this kind, where there has been no delirium or coma and where relapses have not occurred, recovery has been the rule.

Circulatory system.—The pulse-rate had varied greatly in different cases. As a rule it has been much accelerated. In a number of cases the pulse has been slow, in a few ranging as low as 40 to 50 per minute. Marked variation in its frequency at different hours of the day and on consecutive days has been frequently observed in the same individual. The pulse-rate is ordinarily little influenced by alterations in temperature. In two cases which recovered its rate remained normal during the whole course of the disease, although the temperature throughout the illness was considerably elevated. In the early stage the pulse has been full, regular, and of good tension, and it remains good in cases which recover. In chronic cases it becomes rapid, irregular, and of poor tension. Several hours before death in acute cases the pulse has usually become very rapid and feeble. This has been associated with lividity of the body. No changes in the heart sounds are observed beyond what are common in all wasting diseases.

Respiratory system.—The respirations as a rule have been accelerated at the commencement of the illness, always absolutely, but frequently also out of proportion to the acceleration of the pulse, though no lesions of the lungs could be detected on auscultation. This has been one of the conditions which produced the resemblance of the patient's appearance to that of one suffering from acute pneumonia. In those cases in which the pulse-rate has been slow at the commencement the pulse-respiration ratio has been as high as 1 to 2 or even higher. In the acute cases various forms of nervous breathing were frequent, particularly in young children, and shortly before death. True Cheyne-Stokes breathing was very rare, but the various modifications of this, such as that where the breathing rises gradually to a maximum, falls suddenly to a minimum, rises slowly again, and passes through cycles of irregular length, have been not infrequent. In some of these the pulse has followed the respiration, and in some not. How far these irregularities of the respiration have been pain reflexes in a patient in a state of stupor is naturally not clear, but a number must undoubtedly be placed under this category. In the acute cases immediately prior to death, intermittent, sighing, and irregular respiration have been frequent. In chronic cases the breathing has generally been quiet.

Digestive system.—Vomiting has been the most prominent symptom of disorder of the digestive system. A history of this has been almost uniformly obtained. It commonly ceases after the first few days, but in chronic cases it may occur at intervals without reference to the pyrexia. In those cases, however, in which relapses occur it has been a feature of the periods immediately preceding the recrudescence of the fever. It has occurred with little effort and without apparent nausea. Unless throughout the first few days, during the acute stage of the disease the appetite has as a rule been good and considerable nutriment has been taken, and often with apparent relish. The occurrence of vomiting seems to have interfered very little with the taking of food. The fæces in general have been quite normal, showing no evidence of incomplete digestion. Throughout the course of the disease the tongue, as a rule, has been fairly clean, with perhaps a thin white moist fur. In very severe and protracted cases only has it been dry and brown. It has been observed to peel in an irregular and patchy manner in some cases. The abdomen has never been distended, nor has the spleen impossible to get the girl to tell truthfully why she had inflicted such a peculiar form of punishment upon herself.

On Nov. 20th I removed a needle from the left breast of this patient, making in all 42 needles and two pins removed during the course of 13 months and by means of four major and four minor operative procedures. Shortly after this slight operation she began to complain of nausea. Her general health was bad and she rapidly lost flesh and strength. Soon she became unable to retain nourishment and was put to bed. Abdominal distension was marked and vomiting became persistent. It was evident that intestinal obstruction, due to adhesion, was rapidly being established. Rectal alimentation was undertaken and, together with gentle stimulation, was successful in bringing her strength up to a point where operation for the relief of the obstruction was possible.

On Dec. 14th I performed the fifth laparotomy. The abdomen was opened through the scar of the second and fourth laparotomies. A rapid survey of the abdominal cavity disclosed the obstructed area of the small intestine. The mass of coils was quickly freed of its numerous adhesions and the peritoneal toilet completed. As much as possible of the old cicatricial tissue was excised and the abdominal wound was closed with layer sutures of plain No. 2 catgut. Interrupted sutures of kangaroo tendon were placed in the muscular and fascial layers and the skin edges were approximated with a subcuticular suture of No. 1 catgut. This was the only one of the five laparotomies in which the material used for the closure of the wound was other than plain No. 2 catgut. I mention this merely because it is a singular fact that in the only case in which I used *unusual* precautions to guard against post-operative accident the precautions did not avail. On the following day the patient's temperature rose to 103° and she was slightly cyanosed. Examination of the chest discovered subcrepitant râles and prolonged high-pitched respiration over the upper and middle lobes of the right lung. She complained of no pain but was quite apathetic. 48 hours after operation the patient was seized with a violent and uncontrollable fit of coughing and immediately collapsed. A hasty examination disclosed the fact that, in spite of the strong suture material used and the extra precaution of a firm abdominal binder of adhesive plaster, the intestines were protruding. The patient was immediately taken to the operating room and under nitrous oxide and oxygen anæsthesia I repaired the abdominal wound with through-and-through sutures of kangaroo tendon and silkworm gut. Artificial respiration was repeatedly necessary during this procedure and only the most vigorous stimulation availed to prevent her death upon the operating table. The possession of an almost incredible vitality enabled her to rally, and 24 hours after this secondary suturing she was conscious and gradually gaining strength. Auscultation revealed complete consolidation of the upper and middle lobes of the right lung. With a dogged courage and tenacity which were a revelation to me the patient fought for her life until, overwhelmed by the pulmonary infection and the drain consequent upon the attempt to repair the abdominal wound, and vainly striving to throw off a hitherto unsuspected tubercular focus, she succumbed on Dec. 30th, 16 days after her last operation.

At the post-mortem examination a thorough fluoroscopic examination of the head, the neck, and the extremities revealed no foreign bodies. The following are brief details of the examination:—

Thorax.—Heart: Normal. Left lung: Intense hypostatic congestion and a few scattered tubercles. Right lung: Upper and middle lobes filled with tubercles and small cavities containing pus and cheesy detritus; lower lobe practically normal. Mediastinum: Normal save for a few slightly enlarged lymph nodes. Pleural cavities and pericardium: Normal.

Abdomen.—Abdominal wall: The wound of the last laparotomy was unhealed and the edges were dark in colour and dry. Very little granulation tissue had formed. Peritoneal cavity: In the left ilio-inguinal region there were some peritoneal inflammation and a small quantity of thin greyish pus, offensive in odour. A similar condition was met with in the pelvis. The general peritoneal cavity was walled off from these two areas by matted intestines and was normal. Viscera: The spleen, pancreas, kidneys, ureters, and pelvic organs were normal. *The liver*: On the upper surface of the right lobe at a point about two inches from the suspensory ligament and the same distance from the anterior border was a spot marking the point of attachment of an old adhesion. Incision into the substance of the liver at this point brought to light a bit of steel half an inch long, the remainder of the needle of which I removed a part at the fourth laparotomy. Immediately behind this was another needle, intact, two and a half inches in length. Both of these pieces of metal were almost disintegrated by rust. It is a curious fact that the hepatic tissue was as devoid of signs of irritation as though the needles had been thrust in after death. The rest of the liver was normal and contained no foreign bodies.

The gastro intestinal tract.—Œsophagus: There were no dilatations strictures, ulcers, perforations, or scars. Just above the cardiac opening of the stomach an area about two inches in width and embracing the entire circumference showed unusual and intense pigmentation. Stomach: The mucous membrane showed merely the changes of a chronic gastritis. No ulcers were present. It is worthy of note, from a surgical standpoint, that the silk sutures placed in the stomach wall some 12 months previously to death were almost entirely absorbed, their situation being marked only by a few disorganised silken threads. The small intestine: A thin, transverse cicatrix indicated the point at which the enteroplastic operation at the third laparotomy had been done. At this point also the Lembert stitches had undergone absorption. Aside from several scars upon the peritoneal surface of the small intestine nothing else worthy of record was found. *The large intestine*: The puckered scars, already referred to, were the only abnormal features. The retroperitoneal tissue: In the median line, lying transversely upon the left renal vein, was a complete needle. It was entirely intact, except for a break a quarter of an inch from each end. These two little fractures allowed it to accommodate itself to the rounded contour of the vein. When the needle was removed I found it to be exceedingly friable, and it seems reasonable to believe that it was broken by the repeated hammering of the transmitted pulsations of the renal artery.

The *source* of some of the needles is still a question in my mind. A great majority of those found in the abdominal cavity were undoubtedly swallowed; she admitted this and their position in reference to the gastro-intestinal tract bore her out in her statement. At times, however, I had detected tiny red spots upon her abdomen which I believed to be the points of entrance of needles thrust into her body through the skin. She absolutely denied this, however, and as she had never been detected in the act this must remain a pure conjecture. The group of needles in her arm, too, would suggest some such procedure, although the migrations through the tissues of foreign bodies of all sorts have been the source of much comment and are, indeed, astonishing in their extent.

The *motive* which compelled this strange diet is also conjectural. Hysteria is undoubtedly the keynote. The assumption that her acts were in the nature of serious attempts to destroy herself is unwarranted. She said that family troubles were the cause of her peculiar actions and slyly intimated that she wished to commit suicide, but her manner during her confidential outbursts was not convincing. She told me, in all seriousness, that she had made several attempts at self-destruction previously to swallowing the needles but in every instance she fell suspiciously short of accomplishing her end. The notoriety to which she readily subjected herself appealed to her strongly and she felt that her position as a "celebrity" was indeed an enviable one. Another feature of interest is this: she had no areas of anæsthesia or of demonstrable paræsthesia, hence the presence of the needles must have caused distinct sensations of some sort; perhaps, in addition to the undoubted hysterical condition, or as part of it, there existed a perverted sexual appetite which found its gratification in sensations that normally would produce only pain. Incidentally, while she was under observation, the patient's menstruation was most irregular. She was the only one who could positively solve the problem of the motive. She was quite an entertaining person. The stories she had to tell of the various members of the medical profession with whom she came in contact, and her unconcealed mirth at their vain attempts to diagnose her case correctly, showed a sense of humour which, while certainly perverted, was remarkably acute. When not ill or in pain she was cheerful and happy. She took a childish pride in the extent and magnitude of the various operations to which she was subjected. But with all her perversity there was an undercurrent of shrewdness that was positively baffling. Naïve, irresponsible, roguish, sullen, and morose by turns, grateful always, she had won the personal interest and sympathy of her medical attendant by her unswerving loyalty.

I am indebted to Dr. John Aspell, upon whose service this patient was first admitted to Fordham Hospital, for the opportunity to see and report this interesting case. Dr. George Roe Lockwood kindly allowed me the use of the x-ray plates taken under his direction.

The literature of pins, needles, and other foreign bodies introduced into the body is large, but I have been able to find few cases which closely resemble this one. The following reported cases are of interest in this connexion.

Dr. Joseph D. Craig of Albany has kindly sent me a copy of a paper[1] in which he describes a case which resembles in some respects the one which I have reported. The following is a brief *résumé* of his case. A woman, aged 24 years, single, insane, but in fair physical health, paper was admitted to Fordham Hospital, New York. She was 23 years of age and married. Her illness at that time was referred entirely to her stomach. Attempts at eliciting a satisfactory history from the patient were met, in the main, by sullenness, evasion, and apparently deliberate misstatements. I learned, however, that she had been the subject of surgical attention at different times, the extent of her operative treatment having been such measures as repair of a cleft palate, removal of the coccyx, and uterine ventral suspension. She stated that she had always been exceedingly nervous, was occasionally the subject of convulsions, and had never had any illness resembling her present trouble. She had been sick for a week previously to her admission to the hospital with gradually increasing pains in the region of the stomach and persistent vomiting. The vomiting seemed to bear no relation to the ingestion of food and neither relieved nor aggravated the pain in her stomach.

---

[1] Read before the Medical Society of the County of Albany on Feb. 10th, 1892.

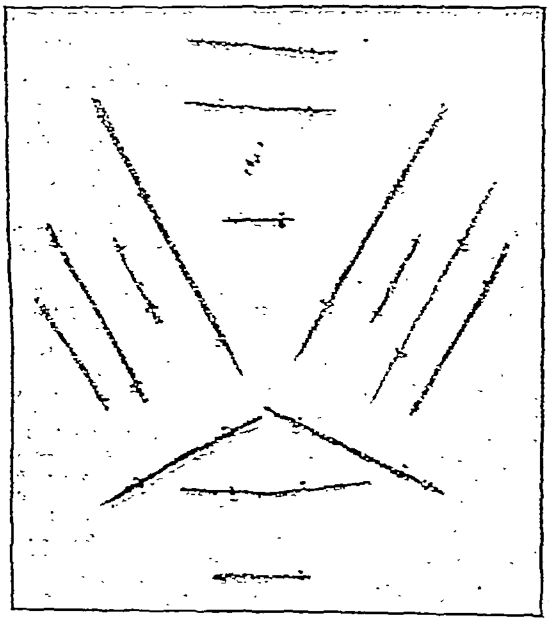
Examination showed the evidences of the above-mentioned operations and, aside from the fact that the patient was of an extremely hysterical type, directed attention to the abdomen. There were several small scars over the stomach the presence of which she either *could* not or *would* not explain. The entire abdomen was distended and tender, and rigidity in the upper portion was particularly marked, but I made out no intra-abdominal mass. Vaginal examination showed merely a normal uterus and appendages in an abnormal position, and a point of tenderness immediately behind the cervix in the posterior vaginal fornix. The temperature was 99·6° F., the pulse was 88, and the respirations were 20. Urinalysis indicated normal kidneys.

In the light of later events the character of the tenderness and rigidity of the abdominal area is interesting. The *tenderness* upon the lightest and most superficial touch was apparently exquisite, was most marked over the region of the stomach, and was a little more marked to the left of and below the umbilicus than in a similar region to the right. It was noticeable that the *rigidity* disappeared when the patient's attention was diverted to another place. These two facts, the exaggerated superficial sensitiveness and the fleeting character of the rigidity, taken in consideration with the general demeanour of the patient strongly suggested hysteria as the sole explanation of her trouble. In addition to these facts the cicatrices of the operations already performed, coupled with the patient's repeated demands for "surgical treatment," as she herself put it, tended to strengthen further the presumption that she belonged to the class of hysterical women who have compelled that phrase of medical slang "operation crazy."

On the day following her admission the patient vomited about three ounces of bright red fluid blood, unmixed with food of any kind. She was not seen in the act of vomiting but an immediate examination failed to reveal any bleeding point in the mouth or pharynx and there was no evidence of epistaxis. Gastric sedatives were administered and a restricted diet was ordered. A normal bowel movement was obtained. On the second day after admission the patient again vomited some blood, this time mixed with a little food. In the afternoon of this day she also had a general irregular convulsion with opisthotonos. On Oct. 29th she vomited frequently, the vomitus always containing a little fluid blood. Her convulsion was repeated and overcome by gradual digital dilatation of the sphincter ani. This measure proved valuable in both a curative and prophylactic manner for she was never again affected in a similar way. On the 30th the vomiting continued. The temperature at no time rose above 100°, and the pulse afforded no guide to the general condition of the patient, as it varied from 80 to 140 per minute with no apparent cause. On the 31st, being unable to explain the presence of blood in the vomitus by a diagnosis of hysteria, and bearing in mind the fact that a great many of the cases of gastric ulcer occur in highly neurotic patients, the tentative diagnosis of such a condition was made and operation for its relief was undertaken. When the patient found that an operation was considered advisable she appeared quite satisfied—a feature of the case which was not at that time properly appreciated.

Under ether anæsthesia I opened the abdomen through the sheath and fibres of the right rectus abdominis, the incision extending from the free border of the ribs downward for about three inches. The fingers of the exploring hand came in contact with an omental adhesion fixing the stomach to the anterior abdominal wall. At this point was a hard mass which was removed and found to contain an ordinary cambric sewing needle very much corroded. Further search brought us immediately upon another needle protruding from the stomach itself, half an inch from the greater curvature and about two inches from the pylorus. Part of this needle was in the cavity of the stomach and part was protruding into the abdominal cavity, the extra-gastric portion being entirely protected by a small omental graft. So roughened and corroded was this needle that in order to remove it an incision was necessary, the stomach wall being split for about half an inch. This small opening was sutured with a single row of the ordinary Lembert stitching, black silk being the material used. Two other needles were found perforating the stomach nearer to the lesser curvature and about equally distant from the cardiac and pyloric extremities. These were removed and the resulting wounds treated in a manner similar to that described above. Lying between the folds of the gastro-hepatic omentum were two more needles. Here I merely split the peritoneum, removed the needles, and whipped the resulting raw surfaces together with a continuous suture of No. 1 catgut. Continuing the investigation downward, the transverse colon was next encountered. This was bound to the parietal peritoneum by numerous delicate adhesions which were thoroughly organised. The wall of the colon was dimpled and pitted in several places by little puckered scars, the origin of these scars being immediately made manifest by the discovery of four needles in different stages of emigration from the large intestine into the folds of the great omentum. Each of these needles was treated as follows. The intestinal coat was incised sufficiently to allow removal of the foreign body and then was closed by a single row of Lembert stitches of black silk. Proceeding downwards from the colon the omentum was next examined. It was found to be quite adherent to the abdominal wall and was gently freed by means of the fingers. It contained six more needles. These were clustered together in the lower left quarter of the omentum and a simple resection of the needle-bearing area was resorted to. In order to continue the exploration I had found it necessary gradually to enlarge the original incision as more room was needed, and it now reached to a point one and a half inches below the level of the umbilicus. The general transmuscular character of the incision was preserved throughout. In palpating the abdominal wall from within, four more needles were found lying in the parietal peritoneum at the point of the union of that membrane and the omentum. They were gathered together in an area three inches in diameter just to the left of, and below, the umbilicus. In nearly the same position on the right side of the

FIG. 1.



Needles removed at first operation. The reproduction of the photograph shows well the extent to which they were corroded.

discovered. The woman had no recollection of having swallowed any such thing, but said that she was in the habit of putting pins in her mouth.

Dr. Forbes Hawkes[13] reports a case which has traumatism as its essential feature. An Italian labourer sewed a button on his vest and then stuck the threaded needle in his cravat. He indulged himself in true Italian style by fighting with some compatriots and received a sharp blow upon the epigastrium. He experienced a pricking sensation and a few days later noticed a scratch over the region of his stomach. Ten days later the man became quite ill, and all symptoms pointing to some grave intra-abdominal condition laparotomy was resorted to. An abscess cavity was found beneath the liver and from this a pint and a half of greenish pus and one needle, threaded, were evacuated. Recovery followed.

Dr. Charles H. Peck[14] removed a long upholstery tack from the appendix of a patient who had suffered from recurrent attacks of appendicular colic. He reports that while the appendix contained two fæcal concretions in addition to this foreign body, there was no inflammation.

The low mortality of cases of this nature is indeed surprising. In the two cases of insanity which I have quoted above it is distinctly stated that the presence of the foreign bodies did *not* contribute to the fatal result, in spite of the variety and multiplicity of the objects found.

The two cases reported by Dr. F. C. Bottomley[15] would seem to offer negative proof of the statement that there is "safety in numbers." The first was that of a man, 56 years old, who had for four days suffered great pain in his back, high up between the shoulder blades, and had had several attacks of hematemesis during that time. When admitted to the Royal Free Hospital, London, the temperature was 102° F. and for the two days between admission and death he suffered excruciating pain and had repeated attacks of bloody vomiting. The patient's temperature ranged between 102° and 104° and he died after an illness of only six days' duration. The post-mortem findings were as follows. The upper dorsal portion of the aorta was perforated by a broken needle which also lay partly in a cavity between the aorta and the œsophagus. This cavity was small, was filled with blood and clot, and had a direct communication with the canal of the œsophagus. The second case was that of a woman, aged 35 years, who suddenly collapsed in the street. She was taken to the same hospital and examination revealed a tent-like, pulsating swelling over the cardiac area. A small incision was made over this and a needle, an inch and a half long, was removed. The woman regained consciousness and gave the meagre information that she had had pain in her left breast and had noticed a "tumour" for two days previously to her attack of syncope. Shortly after talking the patient became cyanosed and restless and died. The post-mortem findings were as follows. A pericardium distended with three-quarters of a pint of blood; a perforation a quarter of an inch in diameter situated at the base of the right ventricle, near the origin of the pulmonary artery; numerous scratches elsewhere upon the wall of the right ventricle.

An interesting necropsy finding is reported by Dr. Charles J. Cooke.[16] A girl, aged eight years, swallowed a needle. Four days later Dr. Cooke found her suffering from meningitis, from which she died after having been under his care for six days. A necropsy showed a needle an inch and a half long imbedded firmly in the posterior wall of the pharynx on a level with the floor of the nasal cavity. It projected upward and backward. Manipulation dislodged it before accurate observation of the position of its upper end could be made, but Dr. Cooke believes that it penetrated and infected the sheath of some nerve and produced, by extension of the infection, the fatal meningitis which was demonstrated.

Such an interesting subject as the ingestion of pins and needles could scarcely be dismissed without mentioning its connexion with the much-mooted question of the causation of cancer. Dr. Knott's paper, quoted above, contains this paragraph: "Godelias and Moniere have each recorded a case of cancerous stricture of the œsophagus attributable to the swallowing of a pin a long time before. In each case the pin was found imbedded in the cancerous mass."

New York.

A STUDY OF FIVE CASES OF APPENDICOSTOMY.

BY J. LIONEL STRETTON, M.R.C.S. ENG.,
L.R.C.P. LOND.,
SENIOR SURGEON TO THE KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.

THE operation of appendicostomy has been described as of the simplest possible nature—"a small button-hole incision through which the finger is passed and through which the appendix is withdrawn and fixed in position." This proceeding may be possible in some cases, but my experience is that the finding of the appendix is not so easily accomplished. There is no certainty as to its situation or condition. In three of my five cases (Cases 1, 2, and 5) it was curved and adherent, and in neither of them could it have been brought out of such an incision. I have found it preferable to make an opening sufficiently large to allow of easy manipulation, and latterly I have increased this in order that I may make a thorough examination of the abdominal contents. The increased risk is infinitesimal, while the conditions indicating the desirability of the performance of the operation are often obscure. With an incision of the length which I advise it is possible to fix the appendix in the most suitable position for the future passage of the catheter. I fix it outside by means of a pin passed through its mesentery and close the wound round it in layers, being careful not to constrict it too tightly. It is a disadvantage to put any sutures through its walls. It may be amputated at the end of 48 hours, but in future cases I shall leave it for a fortnight or three weeks unless there is pressing need for immediate irrigation. In Cases 1 and 5 its early removal was the cause of wound infection, a risk which must always be present, and if it occurs is a source of considerable trouble. It not only prolongs the process of healing but, owing to granulations and the retraction of the orifice of the appendix, it causes difficulty in passing the catheter and ultimate contraction of the opening. To show that this experience is not confined to myself I may cite a case reported in THE LANCET of Dec. 28th, 1907 (p. 1819), by Dr. J. A. Pottinger, who says: "The catheter was at first removed between each occasion of irrigation, but it was found that even in 24 hours the wound closed so owing to the growth of granulations that it was somewhat difficult to find the opening and latterly a soft rubber instrument was used and left in." Since the operation was brought into prominence in this country I have performed it on five different occasions. The following are the notes of the cases operated upon:—

CASE 1.—The patient, a female, aged 29 years, was admitted to the Kidderminster Infirmary in October, 1905, on account of mucous colitis and obstinate constipation. She had suffered for 14 years and no treatment had benefited her.

On Nov. 7th the appendix was exposed through the usual incision. It was a long appendix, curved, horseshoe-shape, which necessitated dividing the meso-appendix to bring it out. A suture on each side fixed it to the skin. On the second day after the operation the appendix was cut off level with the skin and irrigation was commenced with a satisfactory result. The orifice of the appendix sloughed and by the end of a week it was impossible to find a passage for the catheter. A second operation was performed in order to fix the orifice at the skin level, and a piece of indiarubber tube was left in for a few days. The patient complained of the pain caused by the passage of the catheter and became so unruly that it was found advisable to discharge her on Jan. 18th, 1906. The orifice to the appendix was then visible. She returned, however, in May and begged to have the part reopened. On examination the orifice had completely disappeared. Under ether the cicatrix was excised and the orifice was discovered immediately beneath. It was sutured up to the skin and irrigation was commenced. The patient was soon able to pass the catheter to perform the irrigation herself and she derived great benefit therefrom. The bowels acted freely and there was much less mucus. She was discharged on the 25th. On March 28th, 1907, she returned again. She had allowed the opening to contract almost to a pin point. With great difficulty a fine probe was introduced and then a No. 1 catheter. It was dilated up to No. 5 and irrigation was again commenced. She was cautioned as to the necessity of keeping the orifice patent and again discharged, but she had not the courage to continue the treatment. She was seen again in October when the orifice was found to be contracted as it had been in March. It was evidently quite useless to persevere any further so I decided to perform an ileo-sigmoidostomy.

CASE 2.—The patient, a female, aged 19 years, was admitted to the infirmary in March, 1906, on account of obstinate constipation. It was impossible to regulate the bowels by drugs and diet.

On April 3rd the appendix was exposed through an oblique incision; it was curved (horseshoe shaped) and the tip was adherent posteriorly. It was brought out and fixed by a pin through its mesentery. The abdominal wound was closed in layers. On the fourth day after the operation the appendix was cut off level with the skin; on the fifth day the pin was removed and irrigation of the bowel was commenced. The administration of a pint of water with half an ounce of sulphate which time she was occasionally nauseated and sometimes vomited. About March 5th she vomited a small quantity of blood unmixed with food. At this time facilities for x ray work were available and skiagraphs were made of both thorax and abdomen. The picture of the abdomen showed the presence in an unaltered position of the needle in the cul-de-sac of Douglas described in the early part of this paper. No other foreign bodies of any sort were shown in the photographic plate. The x ray picture of the thorax and neck showed nothing unusual.

The making of the x ray plates was apparently a form of investigation which, to the mind of this particular patient, was of a nature entirely too intimate and searching and she refused further treatment and left the hospital on March 10th in good general physical condition.

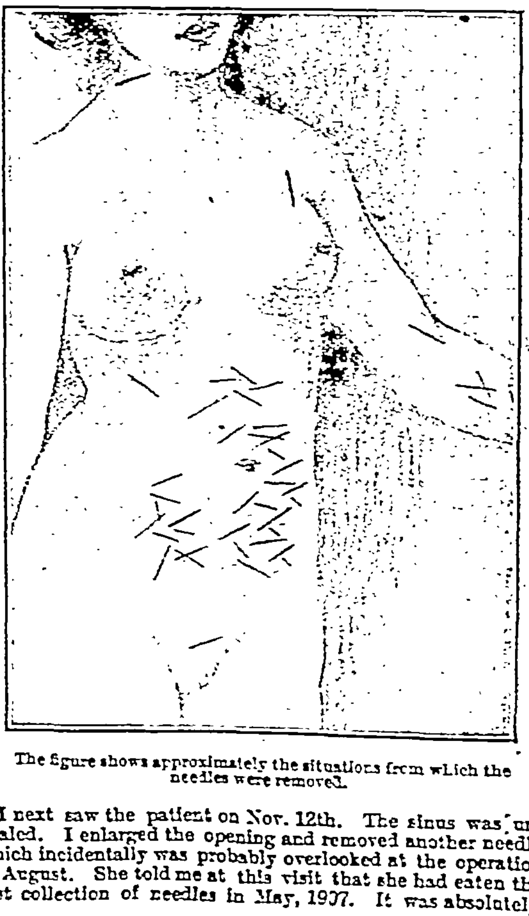
On April 12th the patient came to my office and told me that she was becoming nauseated again, that she had "discovered" another needle—in her neck this time—and that it was giving her trouble. The foreign body was easily felt just behind the ramus of the jaw and the slightest pressure upon this point brought on an attack of vomiting. The x rays failed to show this needle because it lay about a quarter of an inch above the upper limit of the x ray picture. Under cocaine anæsthesia, at my clinic at St. Vincent's Hospital, I removed this needle which was lying immediately under the skin with its point directed horizontally inward and backward. Undoubtedly the presence of an irritating foreign body in the immediate vicinity of the pneumogastric nerve would be sufficient to cause nausea and vomiting. Blood could readily appear in the vomitus, inasmuch as the internal end of this needle was in direct relation with the lower portion of the pharynx. The little wound in the patient's neck healed quickly. She took a position as domestic and discharged her ordinary duties without any difficulty. On May 17th a small abdominal-wall abscess required opening and drainage. This procedure, she proudly informed me, constituted her *eleventh* operation.

On June 20th the patient came to see me again and was in good health. She said that she felt well and her appearance confirmed her statements. She told me at this visit that she had at first experienced trouble from "eating" the needles about three weeks after she had swallowed them and that the first unpleasantness was the formation of a large abscess in her neck, undoubtedly caused by the irritation of the last needle removed. She assured me that she had opened this herself but "could not find the needle." Incidentally she confessed that she had swallowed "six or seven" needles immediately after the second operation, thus confirming my suspicions concerning the one which made its way through the abdominal wall and the two which I removed at the third laparotomy. (Inasmuch as the x rays failed to show the balance of the "six or seven," we must presume that they escaped *per viam naturam* or that her statement was somewhat exaggerated.) She told me, in addition, that she had removed a number of needles as they presented themselves at the surface of her body in the centre of small suppurating spots. A "few" were removed from her neck. At her request I examined a small area of induration deep in the cellular tissue behind and above her left elbow. She thought it was a needle and so did I. She would not submit to examination by the x rays and as she had no pain or tenderness at that point I did not urge the advisability of an exploratory incision.

I felt that the patient was practically through with her operations and was beginning to congratulate myself upon the successful termination of her case, but I was doomed to be disappointed. On June 25th she had a fall from a horse, resulting in an injury to her left arm. The arm and forearm became greatly swollen and suppuration ensued. Again she was admitted to Fordham Hospital. Examination with the x rays revealed several needles in her forearm, one especially long lying in the bend of the elbow. On the 27th, under general anæsthesia, I made an inverted T-shaped incision over the anterior aspect of the arm and forearm and with the aid of the x rays dissected out five needles. The largest one measured two a half inches in length and was situated behind the tendon of the biceps, in immediate relation to the great vessels of the cubital fossa and the elbow-joint itself. The wound was sutured and appropriate drains were inserted. Two weeks later the patient insisted that she had appendicitis. Notwithstanding the absence of the usual symptoms I kept her in the hospital for the purpose of observation.

On July 27th the patient complained that she was too ill to sit up and she was put to bed. She complained of abdominal distress and her abdomen became distended and tender; her temperature rose to 101·5° with a variable pulse and irregular hysterical respirations. On the 31st I opened her abdomen for the fourth time, excising the scar of the second laparotomy. The abdominal cavity was singularly free from adhesions. From the omentum I removed two needles and from the mesentery of the small intestine two more. Beside the ascending colon and just external to it another needle was found and removed. The needle in the cul-de-sac of Douglas, which has already been referred to, was accessible and was removed. I took a needle also from the small intestine. A sharp bar of metal, representing the business end of a safety-pin, *the remainder of which had already been found in her bed*, was removed from an omental adhesion binding the stomach to the anterior abdominal wall. A very stout adhesion firmly fixing the liver to the dome of the diaphragm contained a needle. The difficulty of working in this portion of the abdomen is responsible for my removing only a portion of this, the respiratory movements of the diaphragm breaking it in two in the grasp of my forceps. The portion left behind promptly disappeared into the substance of the liver. At a point over the appendix and in the abdominal wall I found another needle, imbedded in a mass of cicatricial tissue of cartilaginous hardness. This was removed through a separate small skin incision. Systematic search of the abdominal cavity, viscera, and parietes revealed no more foreign bodies. I removed the appendix as a prophylactic measure and for the moral effect which the knowledge of its loss would have upon her. The abdomen was closed in the usual manner with layer sutures. Again the patient's recovery was rapid and uneventful. Slight suppuration occurred in the superficial abdominal cellular tissue. When she had regained strength she was discharged from the hospital with a small abdominal-wall sinus.

FIG. 2.



The figure shows approximately the situations from which the needles were removed.

I next saw the patient on Nov. 12th. The sinus was unhealed. I enlarged the opening and removed another needle which incidentally was probably overlooked at the operation in August. She told me at this visit that she had eaten the last collection of needles in May, 1907. It was absolutely fingers and thumb from right to left and *vice versâ*, he will the more readily find the characteristic small hard mass, and not only detect it but gauge its size and shape and even note the accompanying induration of the stomach walls. In thin babies no difficulty should be experienced, and a plump healthy infant with this condition is not likely to come under medical observation. Prior to my own experience about to be related, although preserving a perfectly open mind on the subject, I doubted whether the true explanation had been arrived at for the pyloric tumours which had been found in the cases treated successfully medically. But now I no longer have any doubt, and I am perfectly satisfied that cases of congenital hypertrophic stenosis of the pylorus can be relieved by medical means and without the surgeon's aid.

Hopeless in regard to medical treatment as the typical hypertrophied pylorus appears to be in the post-mortem room—the tightly shut orifice, the thick gristle-like walls, the cervix and os uteri-like appearance on its duodenal aspect, its capacity securely to hold a dilated stomachful of water—I do not think this after-death state denotes its natural condition during life. I think that tight post-mortem contraction of the hypertrophied circular muscular fibres occludes the pylorus, and this prevents the exit of water when tested in the usual way. Indeed, quite apart from other reasons I know that this must be so, because I have seen the channel patent (No. 4 catheter) during life, even in an extreme case of this interesting condition.

There are two hypotheses as to the causation of congenital hypertrophic stenosis of the pylorus—viz., (1) that this condition is a muscle hypertrophy not only of the pylorus but of the rest of the stomach, and that it is secondary to a functional disturbance (Heubner[2]); and (2) that it is a primary malformation or new growth. Heubner does not state definitely whether his conclusions were based upon his own post-mortem experience; in any case he could not have performed more than one necropsy as he had only one death. And secondly, from the remarks in his paper which was read before the Children's Section of the seventy-eighth Versammlung Deutscher Naturforscher und Aerzte in Stuttgart, he gives the impression that he bases his conclusions on necropsies performed by Wernstedt. He claims 49 cases out of a clinic of 10,000 children. In regard to the two views I am in favour of the congenital hypothesis for these reasons: (1) the condition has been found in the fœtus (Dent); (2) symptoms frequently arise immediately after birth in cases where it is known to exist; and (3) the associated muscle hypertrophy of the stomach is not a general hypertrophy of the organ, or if it be a general hypertrophy of the viscus the part near the pylorus, to the extent of a quarter or one-third of the pyloric end, is immensely thicker in comparison. The stomach being a hollow viscus I think hypertrophy would be general rather than partial if that hypertrophy were due to increased work. It is so, as a general rule, in the bladder with a large prostate, the nearest resemblance to it that I can think of, whatever may be the exceptions to that rule, if there be any. I have made microscopical examinations in three cases and I have found in the pylorus thickening of *all* the muscular layers, including the muscularis mucosæ. The longitudinal fibres were two or three times larger than they should have been, but they were not hypertrophied to the same comparative degree as the circular, which were very powerful. Further, there was an increase in the fibrous tissue, and the submucous layer was larger and thicker than normal. The mucous membrane was healthy. The thickened pylorus ended abruptly at the duodenal side (cervix uteri-like appearance), but gradually tapered off into the stomach walls on the opposite side. On the outside it was constricted in the centre. In the stomach of one case all the layers were hypertrophied, but especially in the pyloric fourth, and the circular fibres were equal to the two others combined. In the others there was considerable hypertrophy of the stomach walls of the pyloric third or fourth. The submucosa was thicker than natural. The mucous membrane was natural.[3]

In regard to naked-eye appearances in this condition the stomach may or may not be dilated, and it is not necessarily dilated in even pronounced instances. On the other hand, it may be very large. Peristalsis may or may not be seen. This occurs in the undilated as well as in the dilated organs, and is best seen when the infant is marasmic, and it is a late, not an early, symptom.

Although symptoms in cases of hypertrophic stenosis often start from the birth, yet this is by no means invariably the case, and sometimes it is one, two, three, four, or more weeks before their onset. The infant then commences to vomit. If this be not checked other symptoms rapidly supervene and steady deterioration results. When vomiting occurs in grim earnest, constipation and scanty urine are its associates. Vomiting may be both irregular as to time and in quantity; the vomit may be small or consist of accumulated feeds. There may be nothing special about the act or the stomach contents may be pumped up violently on to the floor. In a well-marked case bile is absent from the vomit. The stools may be meconium-like, sage green, dark green, dark brown, or tarry. But even these may disappear and be followed temporarily by natural motions. In some cases the symptoms that attract most attention are constipation and marasmus with a dyspeptic background. Prior to all these symptoms, however, it often happens that the child has enjoyed good health and there has been no occasion to suspect any organic gastric malady. Perhaps the baby has been taken from the breast and put on the bottle, and then its troubles began. Although the infant in such cases has displayed no symptoms, I do not think that there is any reason to doubt that the thickened pylorus has been comfortably tucked away all the time. Granted that this be so, why does it suddenly become troublesome?

Cases with classical symptoms of stenosis of the pylorus have succumbed to the malady and post mortem the pylorus has been found normal. The explanation that has been given for cases such as these is that the patients were suffering from pyloric spasm. Granted that pyloric spasm can kill an infant with a healthy pylorus it can as readily accomplish the act with a hypertrophied pylorus. Graft the spasmodic affection on the organic and the explanation of the symptoms is at hand. Perhaps the over-powerful strongly acting pylorus causes congestion or œdema of the overlying mucous membrane with blocking of its lumen, or there may be other explanations for its local congestion, analogous to the congestion of the mucous membrane covering the urethral stricture of a Saturday night reveller. Judged by the irritability of the stomach displayed in these cases the speedy response by waves of gastric peristalsis of regular or irregular rhythm to even so little as the lightest tap over it, it is likely that the pylorus also is in an equally excitable condition. It may be that in such circumstances the mere mechanical irritation of the food tends to keep the pylorus in a constant state of reflex spasm, let alone any toxic action on the muscles or nerve centres that might be supposed to arise from the complex chemical products retained in the stomach. But whatever may be the explanation of the obstruction at the pylorus I have no doubt that the causes for it are as complex and multifarious as are the causes for gastric disturbances that occur in the dyspeptic infant, for it is the dyspepsia that is at the bottom of it, and which is the important factor in these cases. This is not based solely on hypothetical conditions, for have we not pathological evidence to support it? A suckling infant under the care of Bloch[4] was completely cured after having had four weeks' symptoms of congenital pyloric obstruction; he succumbed six months later to an attack of acute enteritis. The pylorus was found just as hypertrophied and just as constricted as in children who die from pyloric stenosis. A study of the vomited matters has thrown no special light on the condition. In some cases there has been no free hydrochloric acid, in others this has been present, in others the vomit has been "intensely acid and sour-smelling," and again in others mucus and lactic acid have been detected, but no free hydrochloric acid.

Dismissing the question of hypertrophic stenosis of the pylorus from the mind for the moment and turning to the infant with a normal pylorus we are daily faced by the problem of how to cater for infants with weak digestions. It is occasionally brought to our notice that the ideal infant food, the mother's milk, is not always the innocuous baby-growing material that it is supposed to be—quite the opposite. There are some infantile digestions that cannot tolerate mother's milk, be it that of the child's own mother or that supplied by foster-mothers—not one foster-mother but a succession of them. Such infants become sick and they was admitted to a hospital for the mentally unsound in 1890. Between the date of her admission and the day of her death, which was apparently caused by pulmonary tuberculosis, she had three profuse hæmorrhages from the bowels and occasional attacks of colicky pains in her abdomen. Careful examination of her abdomen for evidences of malignant disease revealed nothing. She was under observation for six months and symptoms referable to her gastro-intestinal tract were first observed five months before her death. The post-mortem examination brought to light, in the pyloric end of her stomach and in the duodenum, the following remarkable collection of foreign bodies: 51 pins; 16 needles (whole or part); three darning needles; 32 nails, varying in length from half an inch to three inches; two screws, one of them 2½ inches long; three pieces of iron, 3½ inches by ¼ inch; two pieces of wood; two rolls of hair; three pieces of cloth, 5 inches by 1 inch; and six hairpins. The metal pieces were very much corroded. My own case induces me to concur in Dr. Craig's remarks: "These substances are not often used with suicidal intent, but with a loss or *perversion* of the reasoning powers there is an inability to properly estimate the consequences of such an act." The italics are mine.

[3] Reports of the Society for the Study of Disease in Children, vol. v., p. 242, 1905; vol. vi., pp. 27 and 30, 1906.

[4] Quoted by E. Rommo, Jahrbuch für Kinderheilkunde, 1907, vol. xv., p. 477.

Dr. Judson B. Andrews reports[2] the case of another woman, also insane, a morphine *habitué*, whose mental unsoundness was ascribed to menstrual disturbance. She was supposed to have swallowed eight packages of needles just prior to her admittance to the asylum. Three months later needles began to appear at the surface of her body and were removed. In all, during the woman's stay in the asylum, a period of seven months intervening between her admission and her death, the almost incredible number of 288 needles were removed from her body and three were passed from the rectum. A post-mortem exploration disclosed 11 more. They were all rusted. Their presence caused little irritation and did not produce death.

Dr. H. Charlton Bastian of London reported[3] the following interesting case. A woman, aged 55 years, was admitted to the Guisborough Workhouse in November, 1886. She was fairly intelligent but exceedingly capricious and with a disposition which, I should imagine, somewhat resembled that of my patient. She gave a normal menstrual history and had had four children. She had once been confined in an asylum for the insane. She had no morbid appetites. Attacks of epilepsy occurred daily and sometimes she had several convulsions in 24 hours. There was no post-epileptic automatic state. No history could be obtained of any needle-swallowing. In 1887 the appearance of the needles was first noticed, and from that date until the time of Dr. Bastian's paper (Dec. 11th, 1891) 86 needles and one pin were removed from her body after having worked their own way to the surface. One needle was coughed up. As many as 34 needles were removed from her in two months in the year 1891. None were passed from the rectum. At no time was there any suppuration, no extravasations of blood occurred, and she was never made ill enough to go to bed as a result of the presence of the needles. A remarkable fact it is that none of these needles were removed from the right side of her body. A careful examination revealed no anæsthesia on the left side of the body but demonstrated that the prick of a pin was not recognised *as such* on *either* side. She gave absolutely no information concerning the way in which the needles were introduced; such statements as she would make were contradictory and manifestly untruthful. She never complained of any pain and she never vomited any blood.

A case which illustrates the association of sexual perversion and the introduction of needles into the body is that recorded by Dr. George H. Monks.[4] A woman, single, 21 years of age, normal physically, but stupid, was admitted to the Boston City Hospital in 1899. She was very ill, with a high temperature, vomiting, and abdominal pain. She had formed the habit of masturbation and was accustomed to gratify herself by means of massage of the ovaries through the abdominal wall. This procedure finally failed to give her the satisfaction she craved and she perversely hit upon the expedient of inserting hat-pins into her abdomen. An x ray picture showed three of these objects just above the pubic symphysis, apparently driven in the general direction of the ovaries and one in the upper part of the right thigh. All four pins were headless. A minor surgical procedure was sufficient to remove these pins and the recovery of the patient followed. The foreign bodies did not penetrate the cavity of the abdomen.

A great number of cases have been reported in which pins or needles have been swallowed and have been safely passed from the rectum. I suppose every general practitioner has been called at least once to allay the fears and quiet the nerves of some agitated mother whose "baby has swallowed a pin." And sometimes the baby *has* actually swallowed a pin. Such foreign bodies usually pass from the rectum without doing any harm except to the feelings of the family. The only result is that the baby is accorded the same considerate treatment in the matter of handling that is given to an infernal machine. Sometimes, however, these little objects stray from the path of the gastro intestinal tract and give rise to puzzling conditions.

Dr. Sara A. Kime[5] reports the removal, by simple incision, of a needle two inches long, which caused a swelling upon the anterior aspect of a girl's arm. Careful inquiry into this young woman's history disclosed the fact that she had swallowed a needle some 12 years previously to the time she came to see Dr. Kime.

Dr. T. M. Winters[6] of Danville, Michigan, was consulted by a man, 62 years of age, who had an abscess in the groin. Dr. Winters opened this and brought to light a bit of steel two and a half inches long and half an inch in diameter. The patient had no recollection of having introduced this into his body in any way, but his mother vouchsafed the information that he had swallowed it at the tender age of one year.

Dr. J. P. Tuttle[7] reports that a little girl, aged five years, swallowed a bent pin. Ten days later, while voiding urine, the child complained of a sharp pain and upon examination the bent pin was found in the vessel. Dr. Tuttle believes that this pin came from the bladder but also points out the fact that it may have worked its way from the rectum into the vagina.

Dr. John Knott[8] removed a much eroded needle from a swelling on the inner surface of the thigh of a little girl, two years old. The mother said that the baby had swallowed this some nine months before, had immediately had a coughing and crying spell, and that it had caused no further trouble. Dr. Knott also reports two cases of the successful passage of pins in children, one three years old and the other 14 months, the former passing the pin in 16 days with blood-stained stools, while the latter passed the foreign body in eight days without symptoms.

Dr. Frank Hammond[9] of Philadelphia removed from the vagina of a woman, apparently suffering from metritis, a pin which she had swallowed seven months before. The metritis disappeared.

Dr. Arthur DeVoe[10] of Seattle varies the monotony by telling of the safe passage from the rectum in four days of an *open* safety-pin swallowed by a five-year old boy. It had produced no symptoms.

A rather circuitous route was taken by the pin mentioned by Dr. Allan I. Petyt.[11] A man who had had otorrhœa and deafness on both sides for some time was picking cerumen from his ear with an ordinary pin when it "slipped inside." A short time after he had a pricking sensation in his throat. Examination of his ear revealed only the old perforation and a probang passed into the œsophagus produced nothing. Two days later he had some pain in his stomach and three days later passed the pin from the rectum.

Major surgery has not had a particularly prominent part in the removal of such foreign bodies as pins and needles. Indeed, it seems that the protective forces of the body are capable of rising to almost any emergency.

Dr. George Woolsey[12] opened the abdomen of a woman for the removal of a right-sided pelvic mass. The patient had been referred to him as a case of ovarian cystoma. In an abscess, the walls of which were formed of matted intestines, Dr. Woolsey found a pin heavily incrusted with organic material. The inflamed appendix protruded into the abscess cavity, and it is through this organ that the surgeon believes that the pin found its way to the point at which it was accountable for these troubles. On the 6th the opium was discontinued (one and a half minims of tincture of digitalis being substituted). The infant then became brighter and cried more after its discontinuance. On the 7th I again saw the patient with Dr. Munro. Œdema was at that time a marked feature though less extensive than it had been. The erythema had disappeared. The urine contained two parts per 1000 of albumin but there were no casts; it was slightly alkaline when passed and deposited a slight precipitate of earthy phosphates. Dr. Munro subsequently examined the urine and came to the conclusion that there was no deficiency of chlorides. Dr. Munro reported on the 11th that the œdema had quite disappeared since omitting the laudanum. Magnesium sulphate, 0·5 per cent., was now used by him for lavage with the idea that the magnesium base would assist in the elimination of chlorides. Starting on June 8th the child was fed on "humanoid" milk, an Aylesbury dairy company product. He took it well but only in small quantities; 15 grains of cane sugar were added to each feed. He appeared to be more satisfied with the new diet, and he slept well, but the weight fell to 5 pounds 12½ ounces. It was on this date intended to wash out the stomach every 36 hours in place of every 24 hours, as was previously the case. On the 14th Dr. Munro reported that the patient was taking and digesting food well, but "only in small quantities, rarely more than two ounces per feed." He was still losing weight, having dropped to 5 pounds 7 ounces—less than ever. He was sick while being fed once, the first time for a week, there having been no sickness since the 7th. He was ordered a milk-and-water mixture—one part milk and two parts water—every two and a half hours, from two to three ounces at a feed, and to three of the bottles a teaspoonful of cream was added. On the 15th, as the mother was anxious for it, a wet nurse was obtained and mixed feeding was instituted. The infant was sick once on the 16th and three times on the 18th; on this latter occasion coffee-ground vomit occurred, which was thought to be due to cracked nipples. The wet nurse not being a success was discontinued. Lavage was discontinued on the 20th. The child was sick once on the 21st, but not again until the 28th, when he was sick once and then for the last time. During the first week of the milk-and-water diet he had lost 5½ ounces in weight; after that he commenced to forge ahead and gained on an average an ounce a day. He suffered a good deal with flatulence all through the illness, especially after food, and sometimes would cry nearly all day, as if in pain. (After wearing a woollen truss, which was applied in the middle of August, he cried ever so much less.) He perspired a good deal at night. On July 6th the patient was taken to the country.

[12] Annals of Surgery, 1903, vol. xxxviii., p. 950.

The weight of the patient on June 14th, when milk-and-water feeding was started, was 5 pounds 7 ounces, and on July 8th it was 6 pounds 12 ounces. Day by day increasing quantities of milk-and-water were taken; on June 14th the amount was 18 ounces, while on July 6th it was 30 ounces. While on whey the bowels were opened once daily and the motions were green but after the child had been fed on milk and water for a week the stools became quite natural and there were from two to four motions in the 24 hours. Week by week the patient continued to gain ground and by July 27th, when the rectal injections of olive oil were discontinued, he weighed 8 pounds 1 ounce. On August 22nd, when brought back to London, he weighed 9 pounds 8 ounces, and on the 27th, when the nurse left, he weighed 10 pounds and was steadily gaining ground every day. In the middle of September he suffered from spongy tender gums for a week but since impressing the necessity for antiscorbutic foods upon the parents the patient had never looked back. In October he weighed over 16 pounds at seven and a half months and was a jolly, normal baby, and he still (January, 1908) continues to thrive.

A SUGGESTION FOR TREATMENT IN DELAYED CHLOROFORM POISONING.

BY A. P. BEDDARD, M.A., M.D. CANTAB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL; PHYSICIAN TO THE WEST LONDON HOSPITAL.

ALTHOUGH patients suffering from delayed chloroform poisoning may recover spontaneously the literature of the subject shows that the prognosis is bad, which is only another way of saying that the treatment, whether preventive or curative, is unsatisfactory. The clinical symptoms and post-mortem appearances are constant and well established, but their interpretation is still a matter of controversy. Nevertheless, for the purposes of treatment it is necessary to adopt some working hypothesis of the pathology of the condition.

The curative treatment most frequently adopted has apparently been the use of alkalies. This presupposes that an acute acid intoxication of the body is at least an important cause of the symptoms and fatal result. And we must consider whether this is likely to be true. There are many conditions known in which metabolism is so deranged that organic acids produced in the body escape oxidation and are excreted in abnormal quantities in the urine. This state of things is termed acidosis. The body has to provide bases in order to neutralise these acids, and for this purpose it uses either NH_3, the normal precursor of urea, or failing a sufficient supply of NH_3 the inorganic bases in the tissues. The organic acids, such as lactic, β oxybutyric, diacetic, &c., which are intermediate products of metabolism, are not in themselves poisonous; their power of doing the body harm is confined to their action as acids and as long as the body provides sufficient base to neutralise them their presence will not produce symptoms. In other words, acidosis is not a poisoning of the body by acids and it is only when the supply of base begins to fail that acidosis passes into acid intoxication. We know that a high degree of acidosis by the acetone bodies may exist for weeks and even for years, as in acute starvation and severe diabetes, without causing any symptoms of acid intoxication; in fact, we do not know any condition whose symptoms and fatal issue are probably due to an acute acid intoxication, with the single exception of diabetic coma. Even in such a severe disease of the liver as acute yellow atrophy, although an acidosis is certainly present, death supervenes far too rapidly for the symptoms to be due to the acidosis passing into an acid intoxication. This is still more obviously true of poisoning by phosphorus, in which the acidosis is less severe. It is further remarkable what severe and widespread changes may exist in the liver without causing acidosis. For instance, in poisoning by hydrazine, which induces changes in the liver similar to those of phosphorus, no acidosis is present; and the same is true of animals in which multiple necroses of the liver have followed the injections of hæmolytic sera. From these considerations we have to conclude that alkalies could not be of much value in the treatment of delayed chloroform poisoning and clinical experience confirms it.

The weight of evidence is in favour of the view that the poisoning by chloroform is the cause not only of the symptoms but also of the microscopical changes found in these cases. It is, however, manifestly necessary to believe that certain individuals are highly susceptible to the action of chloroform, and the cause of this state of things is equally unknown, no matter whether we call it idiosyncrasy or believe that the vitality of their protoplasm has received some previous injury which has made it unduly susceptible to the action of a general protoplasmic poison like chloroform. Numerous experiments on animals have shown that the action of chloroform on cells is similar to that of phosphorous, arsenic, and other general protoplasmic poisons. Although we do not know how any of these poisons injure cells it is necessary to form some working conception of what changes they induce in the metabolism of the body in addition to the changes caused by the concomitant starvation. The broad facts seem to be as follows. Nitrogenous metabolism is increased—that is to say, there is an increased breaking down of tissue proteid. But the metabolism of nitrogenous substances is also disturbed so that products of proteid catabolism leave the body no longer in a fully oxidised state; consequently the cells have lost to a corresponding degree the power of obtaining energy from proteid. The hepatic glycogen rapidly disappears and to a less extent that of the muscles and other cells; and further the total quantity of carbohydrate in the body is decreased. But in poisoning by chloroform the liver has not necessarily lost the power of forming glycogen, as can be shown by feeding the animals with dextrose. It is therefore clear that carbohydrate metabolism is increased greatly at first and that since the store of carbohydrate material in the body is relatively very small, this increased utilisation must soon come to an end. The facts in regard to the metabolism of fat are well established. Microscopically the cells of the liver, muscles, and kidneys appear to be loaded with fat. In the case of the kidney, however, there is no actual increase of fat; the appearance of the cells is due to a change in their protoplasm whereby fat in combination and thereby masked and invisible becomes obvious under the microscope. In the liver and muscles there is an actual increase of fat which has been transported in the blood from the normal sites of storage and has been taken up by the cells of these tissues. A similar active transference of fat from the depôts to the hungry cells takes place in starvation, but in this case the cells of the liver and muscles do not become loaded with fat; and this must be because they can metabolise it more rapidly. In poisoning by chloroform the cells are starving and call for fat which they take up more greedily than they can metabolise it; and hence, whilst the transference of fat about the body is increased, the metabolism of fat is decreased and we observe under the microscope a fatty infiltration of degenerated protoplasm.

These are the broad facts; and Rosenfeld's interpretation of them has been hinted at and may now be shortly stated. He believes that when cells are poisoned by chloroform their metabolism is so altered that whilst they can utilise carbohydrates well they can oxidise proteids but imperfectly and of magnesium was followed by an action in from five to ten minutes. Various solutions and drugs were tried and it was found that two drachms of olive oil was the most suitable. This acted perfectly and she was discharged on May 4th. I saw her about six months later and I have heard from her medical attendant quite recently. She continues perfectly well, the opening remains patent and gives her no trouble, and the oil still acts satisfactorily.

CASE 3.—The patient, a female, aged 66 years, was admitted to the infirmary in May, 1906, on account of mucous colitis and constipation. Her medical attendant was desirous that the operation of appendicostomy should be performed upon her. She was a well-nourished woman. She complained of pain in the abdomen chiefly affecting the left side, of constipation, and of the passage of mucus. The abdomen was not distended or tender. Per rectum and per vaginam examination did not reveal anything. A large quantity of mucus was passed with the motions.

An operation was performed on May 11th in the same way as in Case 1. The appendix was cut off level with the skin on the fourth day and irrigation was then commenced. The administration of five pints of saline solution followed by two pints of solution of silver nitrate (one grain to a pint) acted immediately and brought away a large quantity of mucus and fæces. This was continued daily. Three days later the opening into the appendix was found to have retracted below the skin to the level of the deep fascia, probably owing to the commencement of irrigation before it was sufficiently adherent. It was still quite easy for us to pass the catheter but it would have been difficult for the patient herself to have done so. On June 3rd (just over three weeks later) it was noticed for the first time that some of the fluid injected escaped by the side of the catheter. This amount increased daily and by the 7th practically all the fluid injected returned through the opening. This caused a suspicion of some obstruction lower down. On the 9th an incision was made in the left side to expose the sigmoid flexure. A malignant stricture was discovered and a colotomy was performed. The patient was discharged on the 21st. The medical attendant informs me that the patient lived about six months and that the appendicostomy opening closed up and did not give any trouble.

CASE 4.—The patient, a female, aged 31 years, was admitted to the infirmary in February, 1907, on account of obstinate constipation. She had had three attacks of pain in the right iliac region since September. Examination revealed some tenderness on deep pressure over the region of the cæcum. Nothing was discovered per vaginam or per rectum.

On Feb. 5th the appendix was exposed through the usual incision. It contained a small concretion and it was brought out and held in position by a pin through its mesentery. The wound was closed in layers, taking care not to strangulate the appendix or its mesentery. On the third day following the appendix with its contained concretion was cut off level with the skin. Irrigation was commenced on the day following. The patient was discharged on March 16th. She was much improved in health and could manage the irrigation quite easily. She has been seen several times since and she continues the irrigation which keeps her bowels regular and she feels quite well.

CASE 5.—The patient, a male, aged 50 years, was admitted to the infirmary in January, 1908. He had suffered for several years from mucous colitis.

An operation was performed on Jan. 8th. The appendix was exposed through the usual incision, three inches long, and the contents of the abdomen were explored with a negative result. The appendix was curved, necessitating partial division of its mesentery; it was fixed in the wound as in the previous case; it was cut off level with the skin on the 11th, and irrigation was commenced. Following this there was a considerable amount of suppuration in the wound necessitating an india-rubber catheter being kept in position. The effect of the irrigation was immediately satisfactory and all the bowel symptoms have disappeared.

In considering these five cases I think I can fairly claim that each of them derived benefit from the operation. In Case 3 it enabled us to diagnose the cause of the mucous colitis from which the patient had suffered and to perform a colotomy for its relief. The patient had been examined by several physicians without the condition being suspected and but for the appendicostomy it would have remained undiscovered until complete obstruction had occurred, when the risk of operation would have been far greater. The case indicates the importance of bearing in mind that mucous colitis may be only a symptom of organic disease. It is for this reason that I advocate intra-abdominal exploration at the time of operation. It has been suggested that the appendix can be dilated sufficiently to act in lieu of a colotomy. This would have been a suitable case for such a proceeding, but I was unable so to dilate it. From my experience I do not think that such a procedure is practicable in many cases.

The result of the treatment in the other four cases has been satisfactory so long as it has been continued. The mucus has disappeared within three weeks of irrigation. The fluid used consisted of two pints of saline solution followed by one pint of silver nitrate solution (one grain to the pint). At the end of three weeks the latter was omitted and a pint of saline solution only was used. In Case 2 it was found that two drachms of olive oil were sufficient to keep the bowels acting. I have seen this patient within the last month and find that this is still satisfactory.

Unfortunately many of these subjects are neurotic and it may be impossible to persuade them to continue the irrigation regularly. If they do not, the orifice is liable to contract; this is the more likely if there has been any wound infection at the time of operation. It is a difficult matter to dilate the orifice and when it is accomplished it will probably be allowed to contract again. The patient in Case 1 was an example of this class. In such cases a more radical procedure is indicated, but the preliminary performance of this operation does not materially add to the risk and gives patients a chance of relief by an operation with a lower mortality.

In none of the cases has there resulted the slightest discomfort. The orifice does not emit any discharge and is easily kept clean. The mucous colitis is easily controlled and the action of the bowels can be regulated with certainty.

Kidderminster.

CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS AND ITS MEDICAL TREATMENT.[1]

BY GEORGE CARPENTER, M.D. LOND.,

CHAIRMAN OF COUNCIL OF THE SOCIETY FOR THE STUDY OF DISEASE
IN CHILDREN; MEMBRE CORRESPONDANT DE LA SOCIÉTÉ
DE PÉDIATRIE DE PARIS.

FOR some time I have been on the watch for a clinical example of pyloric obstruction in an infant which would convince me as to its undoubted hypertrophic nature and which would respond to medical treatment. The case which I presently shall relate satisfies those requirements. I have been well acquainted with dyspeptic troubles in infancy without pyloric hypertrophy which clinically give all the symptoms of that complaint except one important finding, and that is the pyloric tumour. Cases such as these I, too, have had my successes with medically. But if I were to enumerate all my experiences in that respect, then I also would be able to bring to your notice a magnificent array of cases of congenital hypertrophic stenosis of the pylorus in place of this solitary example of a successful case medically treated.

It is but the other day, figuratively speaking, that serious attention was drawn to this condition, and the great number of cases that have fallen to the share of, and have been recorded by, some observers must be due to the inclusion in their statistics of the functional with the organic variety, of the very common with the rare, for it cannot be allowed that hypertrophic stenosis is any other than a rare condition. On the other hand, infantile cases of functional gastric disturbance with symptoms suggesting pyloric stenosis are very common. Some such explanation must be held accountable for the high percentage of cases which have fallen to the share of some writers on this subject in so short a time. But I must confess that I did not think it possible to cure such examples of congenital hypertrophic stenosis of the pylorus as have come within my clinical experience without surgical aid. In the cases of that complaint which I have treated the pyloric tumour was hard like gristle, cut like the cartilage of the knee, was felt through the abdominal wall, the infants were operated upon, and they all died. In the case which I am about to relate the patient presented symptoms and physical signs precisely similar to, and identical with, those just enumerated. By reason of his wasted state and the poor condition of his vitality he was not fit to undergo surgical operation and would, I doubt not, have died if he had been operated upon.

It is remarkable how many recorded cases there are where no pyloric tumour was felt and where the typical appearance was found either at operation or in the post-mortem room. But notwithstanding these repeated failures to detect the tumour during life, I must confess that the diagnosis of congenital hypertrophic stenosis of the pylorus does not satisfy me unless the tumour be felt. Perhaps the failure to find it may in some cases have been due to want of experience of what to feel for, but I think that if greater care had been exercised in making the abdominal examinations the little tumours would not have so frequently remained undiscovered. Granted, however, that due care had been taken, I think I can offer another explanation for failure to feel the tumour. By the usual method of examination—that is, by palpation—the tumour is apt to recede from the fingers and to drop deep down into the abdominal cavity. Now, if in addition to the usual method of abdominal exploration the examiner grasps the abdominal parietes and the underlying parts with the

---

[1] A paper read before the Society for the Study of Disease in Children on Jan. 17th, 1908.

Mr. T. W. Nunn[1] has maintained that the brawny arm results from the obstruction of the main axillary lymphatics by growth within them. This view is doubtless a part of the truth, but it fails to explain why no collateral lymphatic circulation is established to carry on the lymph circulation in the arm. The answer to this question is a corollary to the permeation theory of dissemination in carcinoma. I may be permitted to recall the main outlines of this view of dissemination, which was stated for the first time in my Hunterian lectures for 1905, and more fully in my recent work on breast-cancer.[2] The permeation theory has won such wide acceptance at home and abroad that it may be said to have almost supplanted the embolic theory of dissemination. Indeed, in breast-cancer, the only form of cancer which I have hitherto adequately worked out, the evidence for permeation is so strong that the word "theory" is entirely out of place. When a carcinoma originates, its cells for a time spread by pushing their way into the intercellular lymphatic spaces of the surrounding tissue. This process is known as infiltration. Soon, however, the cancer cells penetrate into the small lymphatic vessels which open out of the lymphatic spaces. Within those vessels the cancer cells find less resistance than in the tissue interspaces, and they commence to spread centrifugally in all directions from their point of origin by actually growing along, and filling up, the lymphatic plexus to which they have obtained access. This process of permeation may slowly spread in a circle any distance up to a maximum of about two feet from its point of origin. It is doubtful if the process of permeation can so completely obstruct the lymphatic vessels as to cause lymphatic œdema. But I have been able to show that a permeated lymphatic is ultimately doomed to destruction by a process which must be included among the reparative efforts of the body against carcinoma. This process may be called peri-lymphatic fibrosis and it takes place as follows. The plug of cancer cells within the lymphatic, continuing to proliferate, finally splits up the lymphatic. Around the microscopic trauma thus produced a vigorous round-celled infiltration occurs, to be replaced later by a capsule of newly formed fibrous tissue, which contracts upon, and ultimately strangles, the inclosed cylinder of cancer cells. The original lymphatic vessel is replaced by a solid, microscopic, fibrous cord, and the process of peri-lymphatic fibrosis is complete.

It thus became evident that *the permeative spread of a cancer is accompanied by an almost co-extensive destruction of the lymph-vascular system.* The recognition of this fact provided for the first time an adequate pathology for the swollen arm of breast-cancer. The circle of permeation, spreading from the breast in the plane of the deep fascial lymphatic plexus, sooner or later reaches the arm and begins to travel down it. After permeation has involved the whole circumference of the arm and has been in turn succeeded by the obliterative process of peri-lymphatic fibrosis, and if, as generally happens, the trunk lymphatics are obstructed by growth of embolic origin in the axillary glands, the arm is utterly cut off from the lymph-vascular system. No collateral circulation can be established, and the lymph can only return imperfectly by percolating the tissue interspaces. The swollen arm of breast-cancer is thus a direct consequence of the actual and complete severance of the lymph-vascular system of the limb from that of the trunk by the conversion of the connecting lymphatics, small and large, into solid cords of fibrous tissue. The change affects first and mainly the lymphatics of the deep fascial lymphatic plexus.

This conclusion appeared a hopeless one as regards the practical problem of relief, and for a long time I could see no solution. Obviously, the limb requires an entirely new set of lymphatics, and the maxim that correct pathology is the key to treatment seemed here to have no application. I believe, however, that I have found a way of providing an artificial lymphatic system for the limb, a system which though clumsy is nevertheless efficient. The details of the method are not yet fully settled and I propose here only to indicate its principles. It was necessary to provide permanent conduits to lead the lymph from the obstructed area into areas of normal lymphatic circulation. But any perforated drainage-tube buried in the tissues is certain to become blocked either by organisation or coagulation within its interior. Was it possible to drain the limb permanently by capillary attraction?

I have in my possession a section of a silk ligature, removed by my friend Mr. J. D. Malcolm, which had been imbedded in the tissues of the peritoneum for ten years. Though eroded at its surface, the main substance of the thread is intact. Moreover, leucocytes are evidently unable to penetrate between the fibrils of the silk, for the interior of the thread is entirely free from cellular elements. Nor is there any microscopic indication of the coagulation of the body-fluids in the interstices of the silk. It appeared therefore, that a stout silk thread, at any rate if not under tension, would remain unabsorbed for some years, and that the absence of organisation and coagulation in the interior would insure the retention of its capillary power. Acting upon these indications, I determined to introduce into the subcutaneous tissue of the swollen arm a number of buried silk threads, running longitudinally upwards from the wrist to terminate in the loose and healthy areolar tissue in or beyond the axilla, and spaced out at convenient intervals around the limb. The operation is closely analogous to the drainage of a marshy field by lines of buried pipes. The success of this plan, though its ultimate result awaits the verdict of time, has exceeded my hopes. The operation required is so slight that even if the relief be but temporary it is worth the cost. But for the reasons above stated I believe the silk will maintain its action for some years.

In a later communication I propose to describe the method fully, to state its results, and to discuss its application to other forms of lymphatic œdema. I am sanguine enough to believe that it will largely replace amputation and arterial ligature in the treatment of elephantiasis, and that it will be successful in relieving women who are chronic invalids from "white leg." Since the operation appears to involve a new principle of wide application it will be convenient to give it a distinctive name. The word "lymphangioplasty" suggests itself as a natural descriptive term for the operation, not as implying any theory of its mode of action but as indicating its practical results. I will conclude by a brief description of my first case, operated upon on Feb. 1st of this year.

The patient, a woman, aged 56 years, was admitted into the cancer wards of the Middlesex Hospital on Jan. 18th last under my senior colleague, Mr. J. Bland-Sutton, who kindly transferred her to me for treatment. In 1894 a portion of the right breast was removed for carcinoma at Chichester Hospital. In 1896 recurrences in the breast and axilla were removed at St. Mary's Hospital. In 1903 two or three small recurrent growths were removed from the axilla. In 1905 the right arm became swollen; it slowly became paralysed, and has been the seat, during the past three years, of excruciating pain which frequently kept her awake at night. On admission there was no evidence of cancer in the body in the form of palpable tumours. The right nipple still remained intact and was not indrawn, and there was no lump in what remained of the right breast, nor was there any axillary mass of growth. The chest and abdomen were free from deposits. The growth was evidently an atrophic scirrhus, which had undergone an almost complete process of natural cure. The right arm and hand below the deltoid insertion were greatly swollen. The œdema pitted slightly on pressure, though it approached the solid variety. There was complete paralysis of the limb, save that the third and fourth fingers could be moved slightly. Sensation was lost in the thumb and first finger, but not in the second, third, and fourth. The hand was warm and of natural colour. Flexion of the elbow was only possible through 15° or rather less.

On Feb. 1st, under chloroform, a number of silk threads, each running upwards from the wrist to the loose tissue upon the chest wall, just below the axilla, were buried in the subcutaneous tissue. The operation produced no general disturbance of note. On the next day it was obvious that the bandages were loose and the strapping upon her fingers was in the same condition and had to be frequently replaced. On the 6th it was noted that the arm and hand were quite flabby and much reduced in size. The skin was much wrinkled and hung awkwardly on the fingers in folds. On the 7th the patient remarked that she "saw her knuckles for the first time for years." The movements of the fingers were beginning to return and she was able to grasp very feebly. The arm was still quite paralysed. On the 10th the forearm and hand began to present an almost normal appearance, but much swelling of the upper arm remained. On the 19th the swelling about the elbow, which as the patient lay was the lowest point of the limb, had somewhat increased, and the limb was ordered to be put upon an waste and would die, and yet they straight away make progress on a preparation of cow's milk that one would not have advocated on theoretical grounds. There can be no question that some milks are toxic in their action, be they breast milk or cow's milk, and feeding with them brings about reflex muscular action and all the symptoms of congenital hypertrophic stenosis of the pylorus.

[2] Cancer of the Breast and its Operative Treatment, by W. Sampson Handley. Murray, 1906.

Dyspepsia in infants is a thing to be avoided, and such dyspepsia is often manufactured by the ignorance and stupidity of those in charge of infants.

If the feeding of the normal infant is a problem in some cases, it becomes additionally so if there happens to be hypertrophic stenosis in the background. In the cases which we are treating daily without this deformity, we are prepared to struggle on and do our best to relieve symptoms. There is no reason therefore why despondency should set in when treating cases of hypertrophic stenosis of the pylorus because they do not quickly answer to treatment. They must be looked upon as difficult medical cases from the outset and dealt with accordingly.

The records of the surgical treatment of this complaint show that the infant does not readily tolerate plastic operations on the abdominal viscera, even at the most skilful and the most expeditious hands. Nor has the medical treatment hitherto been anything to make a boast about. Nevertheless we must for the future, I think, look upon surgery as a *dernier ressort* and not as the sheet anchor of treatment. It is hard upon the surgeons, I admit it, to ask them to galvanise into life a moribund athrepsic infant, and failing in that to take a share in the responsibilities and in the obsequies, but I think in the interest of the patient the surgeon must be thought of late in the case. But once let the physician realise that these cases are not untreatable medically, and there will in the future be more medical successes and fewer surgical failures. What the future will have in store for the cases of hypertrophic stenosis that have been cured medically remains to be seen. In regard to this point, however, it is not uninteresting to learn that Seefisch found that in three cases that responded to this treatment operation became necessary before the children reached the age of 12 years.

Surgery as a mode of treatment for pyloric spasm is neither necessary nor advisable. To operate on such a case would be on a par with performing tracheotomy for the cure of laryngismus stridulus. It is for the purpose of preventing unnecessary operations as well as from the desire to diagnose the case correctly that I attach very great importance to the discovery of the pyloric tumour, and had more attention in the past been paid to its detection there would have been fewer cases on record of congenital hypertrophic stenosis.

Finally, what should be the treatment? It must be conducted on the broad, general principles that experience has taught us to be of value in the uncomplicated complaint. Muscular and nervous hyper-excitability of the organ may be fought by antispasmodics, such as cocaine, opium, chloral, bromide, antipyrin, belladonna, camphor, and sulphocarbolates. I have no special partiality for any of these drugs and I have no supreme faith in their performances. The secret of success in all medical treatment of dyspepsia in infants lies not so much in its drug treatment as in the discovery of the milk best suited to the child. When bottle-feeding is compulsory the selection of just the right form and the right dilution of cow's milk requires careful study, but above all things it must be *clean*. A baby's stomach will deal efficiently enough with a poor milk, but it will immediately resent the stale and the dirty article. And not only should it be clean, but it should be undoctored. The food that is selected should be one that leaves a small residue—one that the gastric juice can readily dissolve. Large lumps of curd in the stomach are fatal to progress.

Regular meals are no less important than restricted meals, and not only are meals that are too bulky to be carefully avoided but the meal must be administered slowly. The dyspeptic infant becomes an inveterate food-bolter, and a meal that is dumped down into the infant's stomach is bound to disagree. The man who is in a hurry to change the dietary because the infant's stomach does not immediately respond to his treatment will never succeed. Success can only be compelled by shaping a course and intelligently sticking to it. It will be found on inquiry that those who claim that they have tried everything have really tried nothing. Ringing the changes on a variety of foods invites dyspepsia, it does not cure it, and such panic-bred dietaries must be avoided.

Abdominal massage in the direction of the pyloric outlet has proved efficacious in at least one case. But in regard to topical treatment gastric lavage has a well-merited reputation. Thorough stomach washing with warm normal saline solution should be used twice a day until the complaint shows decided signs of improvement, when it may be tried once a day. That the remedies are working satisfactorily can be seen by the improved condition of the stools. And there are two other precautions that must be taken—viz., to keep the infant's stomach warm and not to upset his digestion by starchy foods.

But when is the surgeon to be called in? In the present state of knowledge, to assert that the surgeon should never be called in is perhaps not warranted by the facts, but nevertheless I think the advice should be hardly ever, and that the physician will best serve his patient by not being in too great a hurry to shift his responsibility on to his surgical colleague.

On May 22nd, 1907, I saw a male infant, aged two months, in consultation with Dr. D. J. Munro, of Brixton. The history given was typical of the condition of pyloric stenosis. The patient would keep down two or three feeds and then would vomit what appeared to be the whole amount previously taken. He was constipated, had gradually lost ground from the first week of birth, and in spite of being fed on a variety of foods "vomited everything." Various proprietary foods were tried as well as milk and water and peptonised milk, but all with the same result: persistent vomiting followed, accompanied by constipation and the passage of scanty concentrated urine. At a week old the child was breast-fed, took food well, weighed about 7 pounds, and did not vomit, but owing to the mother suffering from a slight attack of rheumatic fever he had to be artificially reared, with the result just related. He was very emaciated when I saw him and seemed so ill that it did not appear that he would survive the night. The pulse was slow and feeble, the respirations were very shallow, the anterior fontanelle was depressed, and the temperature was subnormal. The child was too weak to cry; he opened his mouth as though to cry but no sound came from the lips. He weighed 5 pounds 13 ounces. The vomiting was very persistent and violently expulsive and the bowels were almost absolutely confined.

An abdominal examination left no doubt in my mind as to the nature of the complaint. There was an indurated pylorus of the most typical feel. The lump was located above and to the left (examiner's) of the umbilicus; it was deep down in the abdominal cavity, could be grasped between the fingers and thumb on deep manipulation, was as large as an almond-nut, and felt as hard as gristle. Further, there was on abdominal manipulation obvious gastric peristalsis terminating in the direction of the lump aforesaid. Otherwise there were no physical signs, but there was a right inguinal hernia which had appeared a week after birth. The physical condition of the child was so weakened that it appeared to us that to submit him to surgical operation was tantamount to signing his death warrant. It was therefore decided, with the parents' consent, he should be medically treated, that the diet should be whey, and that the stomach should be washed out daily. On the night of my visit Dr. Munro washed out the stomach with a 0·5 per cent. solution of common salt; this was followed by a four-ounce feed of whey, and subsequently two-ounce feeds every two hours were administered. On the day following and on subsequent occasions the wash was made of sodium sulphate, 0·5 per cent., and sodium bicarbonate, 0·2 per cent., which had the immediate effect of causing regular actions of the bowel. Four-hourly drop doses of laudanum were also ordered. There then had been no sickness for 24 hours and 14 ounces of whey had been retained. Inunctions of cod-liver oil were also instituted twice daily. On May 24th, the second day of treatment, the infant was sick twice following cod-liver oil by the mouth, but 15 ounces of whey were retained. He also passed two dark green offensive motions, the first for four days. On the next day he was ordered teaspoonful doses of olive oil by the rectum, and in place of the drop doses of tincture of opium (which were making him much too somnolent) half-drop doses were substituted, combined with drop doses of tincture of belladonna. The injections of olive oil were mostly all absorbed, but sometimes they were returned with a loose green stool and often undigested. The bowels were opened about once daily and the motions were mostly small, green, and constipated. From May 23rd to June 2nd the infant retained daily the following quantities of whey—viz., 14½, 20¼, 19, 15, 18, 19, 17, 16, 15¼, and 17½ ounces. On the fourth day after commencing treatment he had lost two ounces in weight, but his subsequent gain in weight amounted to 7 ounces—6 ounces during the last five days. The child was sick twice on May 25th, three times on the 26th, twice on the 27th, twice on the 28th, once on the 29th, once on the 30th, and then not again for eight days, when on June 7th he vomited twice. He was fattening visibly. Such was the condition of the patient on June 7th but for several days he had suffered from erythema and œdema and the possibility of this cutaneous disturbance being due to the olive oil injections occurring to Dr. Munro they were discontinued. But the rash still continued to appear for three or four days, so the rectal injections were recommenced but then given once daily only. According to the nurse's description the rash "seemed to appear just after the olive oil injections." The lips became swollen, red patches appeared over the face, rather like port wine stains, and the hands and feet were red and swollen. Besides the swelling of the hands and feet swelling was noticed on the right side of the scrotum; it was, quoting the nurse's words, "quite dropsical," and about two days later it spread over the body. The infant increased in weight, an increase which was thought to be only owing to the swelling just mentioned. By June 8th there was a good deal of dropsy of the neck. He coughed a lot over his feeds and there seemed great difficulty in swallowing and also in breathing. The child was propped up with pillows and often had to be held up by the feet as he choked and "went black in the face" while being fed. The œdema appeared to be obstruction, since hæmatemesis from rupture of greatly distended gastric and œsophageal veins with no alternative channel of venous communication between the portal and caval systems must always be more serious than where one or two alternative paths exist and the total vein bed is divided up to a corresponding extent.

Brighton.

NOTE ON A CASE OF COMPOUND DEPRESSED FRACTURE OF THE VAULT OF THE SKULL; OPERATION AND RECOVERY.

By HANWAY R. BEALE, M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond.,
SURGEON TO THE RETFORD HOSPITAL.

The following case presents some features of interest especially in view of the age of the patient and the amount of damage done to the brain tissue.

On May 19th, 1907, a boy was throwing a piece of iron rod into the air to make it spin and whilst it was up in the air the patient ran out of a house and passed underneath it so that the rod fell endways on to his head. The rod was removed from the head by the patient's father, who said that it had penetrated for a distance of half an inch and blood and brain matter were found on it for that distance. The rod was 17¾ inches long by ⅜ inch square and it weighed 11 ounces. The patient did not lose consciousness. He was taken to the Retford Hospital at once.

On admission the patient was found to be a rather stunted child, six years of age. Although conscious he was decidedly dull and unresponsive to questions. The preliminary examination of the wound did not cause as much crying as might have been expected. Externally all that was seen was a small scalp wound with ragged edges from which some blood was oozing. It was decided to operate at once. The boy was anæsthetised with chloroform and after the usual shaving and cleaning a horseshoe-shaped flap was turned down over the anterior half of the left side of the scalp. This being done, a hole of about the size of a florin was found in the cranium half an inch in front of the parietal suture and half way between the temporal and sagittal sutures. Brain matter was exuding from it. By means of a probe a portion of the bone was discovered buried in the brain half an inch deep and quite detached. This was extracted with forceps and was found to be of irregular shape about half an inch square with jagged edges. On passing the finger round the edges of the hole in the skull it was found that the bone was turned in at the lower and posterior margins of the hole; these portions were raised by means of an elevator and "hinged" into position. The posterior piece broke off in the process and its posterior margin was found to be the coronal edge of the frontal bone; it was half an inch square. The lower piece was of the same area and remained in position. Some trouble was experienced from bleeding from the anterior branch of the meningeal artery but this was stopped by means of a gauze plug. Another spicule of bone three-quarters of an inch long was elevated and removed from the upper margin of the wound. Much blood-clot and hair were removed from the wound and the dura mater was drawn as far as possible across, but as a large portion had been torn away the brain could not be completely covered. The detached pieces of bone were not placed *in situ*. The scalp was sutured up, a small gauze drain being left in the wound. The patient was dressed on the following day. On the plug being removed a small quantity of turbid fluid exuded. He complained of headache, otherwise he was well. On May 23rd suppuration commenced but free drainage was allowed. On June 4th the scalp was suppurating and there was slight hernia cerebri; this was painted every four hours, when dressed, with absolute alcohol. The temperature varied from 98° in the morning to 100° F. at night. Healing was very slow, but the wound gradually granulated over and the hernia disappeared. Finally the skin grew over the wound and recovery was complete. At no period during the time the boy was under observation was there any paralysis or other symptom of nerve lesion. He was discharged on Oct. 5th with the wound completely healed.

The boy was seen in February of this year and he was then well and apparently none the worse for the accident. His school-teacher says that he is rather dull but not more so than before and not more than one would expect of a boy brought up in his poor surroundings.

Remarks.—The vault was involved as is usual in punctured fractures. The amount of damage done to the skull was in excess of that apparent by external examination and the damage to the internal table was more than to the outer. The boy was fortunate in the position of the injury because he just missed having the motor centres damaged. Having regard to the cause of the injury asepsis was almost impossible to attain, and because of this and the detached and buried portion of bone the prognosis was very grave. In many of these cases suppuration ensues and there are formed a cerebral abscess and a localised encephalitis which gradually spreads and death results. Here the suppuration occurred, but there was always a free drainage and thus the risk of subdural or extradural spreading was minimised; apparently it did not occur but remained localised to the area of the wound. It is interesting to note the effect of the absolute alcohol upon the hernia; the granulations were gradually hardened and the hernia shrank in size until flush with the cranium. This method is strongly recommended by some surgeons but others deprecate it; in this case it was certainly of service. The case illustrates the value of the cardinal rule in punctured fractures of the skull in children always to operate as the amount of damage was far in excess of that apparent on external examination.

ROYAL SOCIETY OF MEDICINE.

PATHOLOGICAL SECTION.

Bang's Method of Glucose Estimation.—Parasites of Malaria.—Œsophagostoma Inflatum.

A meeting of this section was held on March 3rd at the Royal Army Medical College, London, Lieutenant-Colonel W. B. Leishman, R.A.M.C., being in the chair.

Lieutenant-Colonel C. Birt, R.A.M.C., gave a demonstration of Bang's Method of Glucose Estimation as published in the *Berliner Klinische Wochenschrift* of Feb. 25th, 1907. Bang's copper solution was prepared by taking potassium carbonate pure, 250 grammes; potassium sulphocyanide, 200 grammes; potassium bicarbonate, 50 grammes; dissolved in distilled water to 600 cubic centimetres with the aid of heat to 60° C., cooling to 30° C., and adding copper sulphate pure, 12·5 grammes, dissolved in 75 cubic centimetres of distilled water, adding water up to 1000 cubic centimetres. 50 cubic centimetres of this was rendered colourless by 60 milligrammes of glucose. It would be possible to titrate with diabetic urine until the disappearance of the blue colour; but it was more exact to keep the unreduced copper in excess and to measure this excess. This was done with hydroxylamine sulphate 3·275 grammes, potassium sulphocyanide 100 grammes, and distilled water to 1000 cubic centimetres. 50 cubic centimetres of this discharged the blue colour in exactly 50 cubic centimetres of the copper solution. The test was thus performed. 10 cubic centimetres of urine (if much glucose was contained in it a measured smaller quantity was diluted to 10 cubic centimetres with water) and 50 cubic centimetres of the copper solution were placed in a flask and boiled for three minutes exactly. The flask was cooled under a water-tap and the hydroxylamine solution dropped in until the last trace of blue colour vanished. On referring to the table the amount of glucose in milligrammes corresponding with the number of cubic centimetres of hydroxylamine solution was seen. The table was necessary since 1 cubic centimetre of the hydroxylamine did not denote a constant quantity of glucose. The reduction of the copper was a function of the time of boiling, of the alkalinity, and of the quantities of copper and glucose present.

The advantages of this process were: the accuracy of the end-point, the stability of the solutions, and the little tendency to reoxidation. The reaction occurred, moreover, in the presence of albumin. Lieutenant-Colonel Birt had employed Gerrard's cyano-cupric method in over 300 estimations and considered it the best adapted for clinical purposes fats even less well. Consequently as soon as the cells have used up their meagre store of carbohydrate, their hungry condition causes a breaking down of tissue proteid and a transference of fat to them; but since neither of these foodstuffs, and especially the fat, is properly utilised, the cells remain in a condition of severe starvation which may rapidly lead to their death through lack of energy. He and other observers have shown that if the poisoned animal is fed with dextrose the transport of fat is prevented because it is no longer necessary; and further, that recovery is much more likely to take place than when the animal is starved. Feeding with carbohydrates, of course, does not prevent the poison from damaging the cells, and it has been found to be useless when protoplasm has been too severely damaged, as in acute poisoning by phosphorus, but carbohydrates do provide the cells with the source of energy which they can most easily utilise, and may therefore prevent their dying from acute inanition and so give them time in which to recover.

If Rosenfeld's theory is accepted as the best working hypothesis of the changes in metabolism induced by chloroform the application of it to man is obvious. It would seem worth while to try feeding such patients with dextrose either by the mouth, or failing this by enemata or continuous rectal infusion of a 10 to 20 per cent. solution, or even by infusing intravenously a 6 per cent. solution. Since these cases are rare and since there is at present no means of knowing which patients will show a great susceptibility to chloroform, it is not likely that it will be possible to decide in man whether feeding with dextrose before the anæsthesia is of any value, but it might be advisable to try it in rickety and ill-nourished children. And, further, it might be possible by inquiry to find out whether an abnormal susceptibility to chloroform is associated with an absence before the operation of such food as will keep up the store of glycogen in the body and whether conditions which reduce this store increase the susceptibility. For it seems clear from experiments upon animals that every chloroform anæsthesia must induce some change in the metabolism and yet the vast majority of patients do not exhibit the serious symptoms of delayed chloroform poisoning.

Seymour-street, W.

A CASE OF CYSTIC DISEASE OF THE MAXILLARY ANTRUM.

By RICHARD LAKE, F.R.C.S. ENG.,
SURGEON TO THE ROYAL EAR HOSPITAL, DEAN-STREET, SOHO, LONDON, W.

THE case about to be described is one that had been under my care at intervals during the last six years and was brought to me by Mr. E. T. M. Tunnicliffe of Finchley.

The patient, a female, aged 18 years, had had five years previously a nasal polypus removed by another surgeon. On Jan. 27th, 1902, when she was first seen by me, the history was that right nasal obstruction had been observed for about a year. On the right hand side a choanal polypus was seen in the post-rhinoscopic mirror and another portion was also visible by anterior rhinoscopy. This was removed by a snare with the patient under anæsthesia and it turned out to be a long thin bilobed choanal (antral) polypus. From this time the patient felt no discomfort in the nose until April, 1905, when she returned with a further obstruction of the right nostril and marked insomnia. On examination nothing was visible at the anterior nares, but a large and extremely translucent polypus was observed occupying the same situation as the former one, though of somewhat greater bulk. A short time afterwards the patient was admitted into a home to have this polypus removed, but during the previous night she had been startled by a tremendous rush of clear fluid from her nose, with complete relief of all the symptoms. Under the anæsthetic, however, a thin, empty cyst-wall was found and removed. The polypus in this case had obviously been cystic. Early in 1906 a second cystic choanal polypus had formed. This was also removed, followed by a considerable flow of fluid. Six months later—that is to say, in July, 1906—a further small cystic polypus was removed under cocaine, obviously coming from the antrum, although there had been no doubt that all the previous polypi had sprung from this situation. About this time the patient began to exhibit signs pointing to pulmonary tuberculosis—that is to say, she lost flesh and suffered somewhat from night sweats and also had a certain amount of cough, but no bacilli were found in the sputum. Although the idea of clearing out the right maxillary antrum was mooted it was postponed, trusting that the tendency to cyst formation might have ceased. As, however, twice during 1907 cystic antral polypi were removed, on Nov. 5th, 1907, the antrum was opened through the canine fossa and the mucous membrane as far as possible was ablated. One large portion, occupying the floor and part of the anterior wall, was removed intact and was found to be closely studded with small cysts containing a straw-coloured fluid, the cyst-walls being extremely thin. The antrum was very roomy. An uninterrupted recovery followed.

The latest paper which I can find on the subject is by Bichaton [1] who gives a *précis* of the literature on the subject. The chief difficulty has arisen from the want of accurate pathological details. Alexander (1897) has had, or seems to have had, the opportunity of examining and reporting upon cases which come under the same category as the present case, for he describes a triple origin for cyst of the antrum, dilatation (*a*) of lymphatic canals, (*b*) of blood-vessels, and (*c*) hypertrophy of the connective tissue. Later Hajeck (1899) proceeded to show that mucocele was a cystic formation proceeding from the mucosa of the sinus. This condition was described in a thesis by Geraldès in 1851. Amongst the various affections which have been grouped together as cystic disease of the antrum according to Jacques and Berteimes (1901) are: (1) development of posterior dental cysts; (2) prolonged and complete occlusion of the ostium (mucocele), the contents sometimes serous, sometimes hæmorrhagic; and (3) cysts arising from the mucosa, fluid viscid and gelatinous.

In the case here reported the cysts were formed from dilated lymphatics. The fluid was *serous*, either pale straw coloured or colourless. The ostium was very patent. The points of chief interest were the connexion between polypus formation and cyst formation and the development of the pseudo-tubercular state, the latter being a not uncommon condition in polypoid degeneration of the nasal mucosa, and according to Waggett [2] in antral suppuration.

Harley-street, W.

LYMPHANGIOPLASTY:

A NEW METHOD FOR THE RELIEF OF THE BRAWNY ARM OF BREAST-CANCER AND FOR SIMILAR CONDITIONS OF LYMPHATIC ŒDEMA.

By W. SAMPSON HANDLEY, M.S. LOND., F.R.C.S. ENG.,
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND; ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL; SURGEON TO THE BOLINGBROKE HOSPITAL, WANDSWORTH COMMON, S.W.

(*Preliminary Note.*)

AMONG the complications of breast-cancer none is more terrible than the brawny swelling of the arm which frequently comes on in the later stages of the disease. The pain to which it gives rise is so excruciating that amputation has been suggested and frequently carried out for its relief. Incisions into the swollen limb have been employed with temporary benefit. No other remedy except the use of narcotics has been suggested. Apart from actual pain and consequent insomnia the discomfort and misery produced by the constant leaden drag of the paralysed, inflexible, and bolster-like limb are important factors in the sum total of misery produced by the disease.

The brawny arm occurs in about one case out of every six of breast-cancer. It was formerly considered to be due to the pressure of a mass of growth upon the axillary veins and this view is still stated with approval in some current textbooks. There are certain facts which go to show that this theory is untenable. During the operation for breast-cancer ligature or excision of the axillary vein has *frequently* been done without the subsequent production of any œdema of the arm. Moreover, the brawny arm often occurs in cases which present no mass of axillary growth, but is rather associated with atrophic forms of the disease. Lastly, the teaching of pathology is that solid forms of œdema are not produced by simple venous obstruction acting alone.

[2] Diseases of the Nose, 1907.

obstruction, since hæmatemesis from rupture of greatly distended gastric and œsophageal veins with no alternative channel of venous communication between the portal and caval systems must always be more serious than where one or two alternative paths exist and the total vein bed is divided up to a corresponding extent.

Brighton.

NOTE ON A CASE OF COMPOUND DEPRESSED FRACTURE OF THE VAULT OF THE SKULL; OPERATION AND RECOVERY.

By HANWAY R. BEALE, M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond.,
SURGEON TO THE RETFORD HOSPITAL.

The following case presents some features of interest especially in view of the age of the patient and the amount of damage done to the brain tissue.

On May 19th, 1907, a boy was throwing a piece of iron rod into the air to make it spin and whilst it was up in the air the patient ran out of a house and passed underneath it so that the rod fell endways on to his head. The rod was removed from the head by the patient's father, who said that it had penetrated for a distance of half an inch and blood and brain matter were found on it for that distance. The rod was 17¾ inches long by ⅞ inch square and it weighed 11 ounces. The patient did not lose consciousness. He was taken to the Retford Hospital at once.

On admission the patient was found to be a rather stunted child, six years of age. Although conscious he was decidedly dull and unresponsive to questions. The preliminary examination of the wound did not cause as much crying as might have been expected. Externally all that was seen was a small scalp wound with ragged edges from which some blood was oozing. It was decided to operate at once. The boy was anæsthetised with chloroform and after the usual shaving and cleaning a horseshoe-shaped flap was turned down over the anterior half of the left side of the scalp. This being done, a hole of about the size of a florin was found in the cranium half an inch in front of the parietal suture and half way between the temporal and sagittal sutures. Brain matter was exuding from it. By means of a probe a portion of the bone was discovered buried in the brain half an inch deep and quite detached. This was extracted with forceps and was found to be of irregular shape about half an inch square with jagged edges. On passing the finger round the edges of the hole in the skull it was found that the bone was turned in at the lower and posterior margins of the hole; these portions were raised by means of an elevator and "hinged" into position. The posterior piece broke off in the process and its posterior margin was found to be the coronal edge of the frontal bone; it was half an inch square. The lower piece was of the same area and remained in position. Some trouble was experienced from bleeding from the anterior branch of the meningeal artery but this was stopped by means of a gauze plug. Another spicule of bone three-quarters of an inch long was elevated and removed from the upper margin of the wound. Much blood-clot and hair were removed from the wound and the dura mater was drawn as far as possible across, but as a large portion had been torn away the brain could not be completely covered. The detached pieces of bone were not placed *in situ*. The scalp was sutured up, a small gauze drain being left in the wound. The patient was dressed on the following day. On the plug being removed a small quantity of turbid fluid exuded. He complained of headache, otherwise he was well. On May 23rd suppuration commenced but free drainage was allowed. On June 4th the scalp was suppurating and there was slight hernia cerebri; this was painted every four hours, when dressed, with absolute alcohol. The temperature varied from 98° in the morning to 100° F. at night. Healing was very slow, but the wound gradually granulated over and the hernia disappeared. Finally the skin grew over the wound and the recovery was complete. At no period during the time the boy was under observation was there any paralysis or other symptom of nerve lesion. He was discharged on Oct. 5th with the wound completely healed.

The boy was seen in February of this year and he was then well and apparently none the worse for the accident. His school-teacher says that he is rather dull but not more so than before and not more than one would expect of a boy brought up in his poor surroundings.

Remarks.—The vault was involved as is usual in punctured fractures. The amount of damage done to the skull was in excess of that apparent by external examination and the damage to the internal table was more than to the outer. The boy was fortunate in the position of the injury because he just missed having the motor centres damaged. Having regard to the cause of the injury asepsis was almost impossible to attain, and because of this and the detached and buried portion of bone the prognosis was very grave. In many of these cases suppuration ensues and there are formed a cerebral abscess and a localised encephalitis which gradually spreads and death results. Here the suppuration occurred, but there was always a free drainage and thus the risk of subdural or extradural spreading was minimised; apparently it did not occur but remained localised to the area of the wound. It is interesting to note the effect of the absolute alcohol upon the hernia; the granulations were gradually hardened and the hernia shrank in size until flush with the cranium. This method is strongly recommended by some surgeons but others deprecate it; in this case it was certainly of service. The case illustrates the value of the cardinal rule in punctured fractures of the skull in children always to operate as the amount of damage was far in excess of that apparent on external examination.

ROYAL SOCIETY OF MEDICINE.

PATHOLOGICAL SECTION.

Bang's Method of Glucose Estimation.—Parasites of Malaria.—Œsophagostoma Inflatum.

A meeting of this section was held on March 3rd at the Royal Army Medical College, London, Lieutenant-Colonel W. B. Leishman, R.A.M.C., being in the chair.

Lieutenant-Colonel C. Birt, R.A.M.C., gave a demonstration of Bang's Method of Glucose Estimation as published in the *Berliner Klinische Wochenschrift* of Feb. 25th, 1907. Bang's copper solution was prepared by taking potassium carbonate pure, 250 grammes; potassium sulphocyanide, 200 grammes; potassium bicarbonate, 50 grammes; dissolved in distilled water to 600 cubic centimetres with the aid of heat to 60° C., cooling to 30° C., and adding copper sulphate pure, 12·5 grammes, dissolved in 75 cubic centimetres of distilled water, adding water up to 1000 cubic centimetres. 50 cubic centimetres of this was rendered colourless by 60 milligrammes of glucose. It would be possible to titrate with diabetic urine until the disappearance of the blue colour; but it was more exact to keep the unreduced copper in excess and to measure this excess. This was done with hydroxylamine sulphate 3·275 grammes, potassium sulphocyanide 100 grammes, and distilled water to 1000 cubic centimetres. 50 cubic centimetres of this discharged the blue colour in exactly 50 cubic centimetres of the copper solution. The test was thus performed. 10 cubic centimetres of urine (if much glucose was contained in it a measured smaller quantity was diluted to 10 cubic centimetres with water) and 50 cubic centimetres of the copper solution were placed in a flask and boiled for three minutes exactly. The flask was cooled under a water-tap and the hydroxylamine solution dropped in until the last trace of blue colour vanished. On referring to the table the amount of glucose in milligrammes corresponding with the number of cubic centimetres of hydroxylamine solution was seen. The table was necessary since 1 cubic centimetre of the hydroxylamine did not denote a constant quantity of glucose. The reduction of the copper was a function of the time of boiling, of the alkalinity, and of the quantities of copper and glucose present.

The advantages of this process were: the accuracy of the end-point, the stability of the solutions, and the little tendency to reoxidation. The reaction occurred, moreover, in the presence of albumin. Lieutenant-Colonel Birt had employed Gerrard's cyano-cupric method in over 300 estimations and considered it the best adapted for clinical purposes inclined plane in an extended position and to be bandaged during the night. On the 24th the limb was continuing to diminish *in size though less rapidly than at first.* Unfortunately, measurements of the limb previously to operation were omitted, so that no accurate record remains of its very rapid and marked subsidence in the earliest days after operation. Its slower subsequent subsidence is recorded in the following table:—

—	Feb. 6th.	Feb. 13th.	Feb. 16th.	Feb. 19th.	Feb. 21st.	Feb. 24th.
Circumference of arm—	ins.	ins.	ins.	ins.	ins.	ins.
At wrist	7¼	6⅞	6⅞	6¾	6½	6⅜
4½ ins. above wrist	8½	8¼	8½	8	7¾	7⅝
Just below the elbow	10¼	9¼	10½*	10¼	9¾	9⅝
3½ ins. below the acromion...	11	9⅞	10½*	10⅜	9¼	9¼

* Temporary return of swelling owing to dependent position of elbow.

Note.—The operation was performed on Feb. 1st.

In conclusion, it may be stated that the patient has lost her pain and that she is very grateful for the operation. Flexion of the elbow is now possible through about 110°, as compared with about 15° or less before the operation. The movements of the hand continue to improve, so that the patient can hold a pin ~~between~~ the finger and thumb. It will be interesting to see whether the muscles of the arm recover their power, but at present there is no sign of this.

My second case was operated upon as recently as Feb. 22nd and it will serve no useful purpose to record it in detail at present. This case, like the former, exhibited within a day or two a remarkable diminution of the tension of the arm and commencing subsidence of the swelling. The patient is already entirely free from nocturnal pain and insomnia.

In conclusion, I may be pardoned for pointing out that the operation of lymphangioplasty is no lucky chance experiment but the definite result of some years of laboratory work in the Cancer Research Laboratories of the Middlesex Hospital. For the opportunities which were afforded me my thanks are due to the Cancer Research Committee of the hospital. Fortunately, the value of lymphangioplasty is capable of immediate proof. If a similar immediate demonstration were possible of the value of the rational method for extirpating breast-cancer in its earlier stages, which I have described and continue to advocate, a method which is also based throughout upon pathology, I believe that a marked improvement in the general results of the radical operation for breast-cancer would be secured and that the field for palliatives such as lymphangioplasty would be correspondingly and fortunately narrowed.

Wimpole-street, W.

PORTAL OBSTRUCTION WITHOUT EXTERNAL EVIDENCES OF PORTAL CAVAL ANASTOMOSIS; ITS PROGNOSTIC SIGNIFICANCE.

BY G. H. CHARLES LUMSDEN, M.B. ABERD.

THE following case of hypertrophic cirrhosis raises certain points of interest in regard to prognosis which seem to justify publication.

The patient, a man, aged 46 years, had for a number of years been addicted to alcoholic excess. During the last five months he had been abstemious, as, to use his own words, "he felt played out." Nothing of any interest could be elicited regarding his previous history and it is noteworthy that he had never suffered from hæmatemesis, but for the past two or three months he had been subject to pyrexial attacks specially at night, though this information was only obtained in response to leading questions. Loss of appetite and occasional morning sickness were also complained of. With these preliminary remarks I arrive at the onset of the present urgent symptom, the hæmatemesis, which ultimately terminated in death. Late in the afternoon of Feb. 25th last I was summoned by the brother of the deceased, who informed me that the latter was suddenly taken very bad with vomiting blood, with the graphic qualification that "the house looked as if it had been converted into a slaughter-house." Picking up my saline infusion paraphernalia and losing as little time as possible I found my patient amid the most horrifying surroundings. It was impossible accurately to estimate the amount of blood lost; one large and one medium-sized basin had been filled, pools of blood had collected in several parts of the room and a great part of the wearing apparel and bedclothes were soaked in blood. In addition a chamber half filled with a watery motion as black as tar was produced for my inspection. These evacuations had occurred within a few minutes of each other, although the patient had not been feeling well for some hours previously and had taken to bed. The pulse at this time was 110, feeble, and easily compressible and the complexion blanched and icteric. The only complaints made by the patient were that he felt faint and could not see. On examination of the abdomen a huge liver presented extending to within one and a half inches of the iliac crest. The lower edge could be readily palpated by all the orthodox methods, felt sharp, and moved freely with respiration. That there was no hepatoptosis was apparent from the upper limit of the liver dulness which extended as high as the third interspace in the mammary line. No distinct enlargement of the gall-bladder could be ascertained and the spleen appeared to preserve its normal size and relationships. There was also an absence of ascites. The lungs were normal, except for slight bronchitis; there were no evidences of aneurysm or organic cardiac disease, though the heart sounds were feeble and short.

The indications for a saline infusion being clear I decided in favour of the intravenous method, choosing the median basilic vein, and with moderate rapidity ran in about three pints of normal saline solution to which five drops of 1 in 1000 solution of adrenalin chloride had been added. The immediate results were extremely gratifying. The patient rallied rapidly, the pulse improved, the sight returned to normal, and the ominous yawning in which he had been vigorously indulging at short intervals ceased. I prescribed absolute rest, the official lead and opium pill as an astringent (?) every two hours, with exclusive rectal alimentation, and left the house with a very fair degree of confidence born of the comforting assurance that death in hepatic cirrhosis was only very rarely due to hæmatemesis.

I called on the patient the next morning, when from all appearances the improvement appeared to be sustained and no faintness was complained of. At a subsequent visit the morning following the only noticeable change was an increase in the jaundice and the patient complained of slight occasional faintness. I anticipated a recurrence of the hæmorrhage and left instructions to be sent for if the faintness increased. The expected summons came the same afternoon when I was informed that the feeling of faintness had increased and that the yawning and dimness of vision had returned. I again injected about two pints of normal saline solution with adrenalin chloride into the median basilic vein of the opposite side with the same hopeful results, though to a lesser degree, and the patient again felt fairly comfortable. Hardly had I left the house, however, when a frightful attack of vomiting occurred. The patient sitting up in bed quite a column of black fluid and clotted blood was projected, I am informed, a distance of about two feet. Several pints must have come up on this occasion. The bowels were again moved at the same time and an identical motion to that of the first day was passed, though in even larger quantity. Subsequently two other large and very offensive motions were passed of a similar nature, death following at a short interval. The urine on examination was found to contain a fair proportion of bile.

It is worthy of note in this case that there were no signs of portal caval anastomosis manifest in the external venous system such as the caput medusæ or even hæmorrhoids. The channel of least resistance to the establishment of a collateral circulation was probably through the azygos and œsophageal veins alone and it is probable that it is from the necessary magnitude which these veins must have attained and the want of any alternative channel that the fatal result was due. The presence or absence of evidences of a collateral circulation through the more superficial venous system and the degree of development of such anastomosis may thus be of very considerable value in prognosis both prior to (supposing there is reason to believe that hæmatemesis is impending) and after hæmatemesis occurring in association with portal this connexion he alluded to the difficulty that often arose in interpreting skiagrams. The line of a fracture might be very indistinctly indicated and very easily overlooked. The normal epiphyseal junctions might be mistaken for fractures, and a little want of care in taking a skiagram might readily distort the shadow and present an appearance of displacement which did not really exist. In reference to treatment he pleaded for a much more frequent use of anæsthesia to aid in the reduction of displacement, he urged the importance of immediate reduction, and he insisted that splints should never be employed for the reduction of a fracture but only for the maintenance of the fragments in their corrected position. The important debateable point, he thought, was connected with the necessity for the exact and perfect adjustment of fragments in all cases of fracture. Pointing out the peculiar construction of long bones and the perfect adaptation of the arrangement of the bony lamellæ for the transmission and distribution of pressure and resistance to the pull of muscles, the question arose whether a perfect restoration of function after a fracture of a bone could be expected unless the replacement of the fragments was so exact as not to cause any interruption in the mechanical adaptation of the bone to its special purpose in the skeleton. It was not easy to give a definite answer to this question, for while a study of the mechanics of the skeleton suggested that the structure of the bones was most closely connected with their function, experience of fractures showed that even considerable alterations in the shape of a bone might, in some circumstances, not be very harmful. He referred, for instance, to the result obtained in fracture of the middle of the clavicle and in Colles's fracture. In the weight-bearing bones of the lower limbs he held that serious deformity of the bone was attended with distinct functional imperfection. Upon the answer given to the question depended the real value of the operative treatment of simple fractures. He thought it should be stated that these operations were not easy, that they were attended with rather more than the ordinary risks of modern surgical operations, that in some cases the mechanical difficulties were very great indeed, and that the use of screws, wires, staples, and plates, while undoubtedly of value, was also attended with disadvantage, for they added to the local injury and lessened the rapidity with which the final repair of the bone was effected. He therefore suggested that when employed the procedure should be of the simplest kind, provided that it was also efficient for its purpose. For example, a wire ligature surrounding fragments would often hold them in place, and, if so, was preferable to anything introduced into the bone. He referred to the value of massage and in reference to movements insisted on the much greater usefulness of active movements than of passive movements, and in conclusion spoke of the great improvement that could be obtained in fractures near, and into, joints by patient and gentle manipulations, and use of the part, when violent movements and rough handling only perpetuated the mischief. He thought there was evidence of a power of compensation for deformity caused by fractures, for some patients who at first were lame after a time lost all lameness and disability; it was an important point to ascertain how far this compensation for deformity could go.

Mr. A. E. J. BARKER said that he was in harmony with the views expressed by Mr. Pearce Gould. The attention of the younger members of the profession should be directed to the possibility of treating fractures without recourse to operation; they should be reminded also that there were other means of diagnosing fractures than by the use of radiography. There seemed to be an idea among the younger members of the profession that a fracture could not be diagnosed without an x ray photograph and that without a radiographer a surgeon was hopeless. In regard to the operative treatment of fractures there were, of course, exceptional cases in which it was justifiable. He himself always wired a patella in the case of a fracture of that bone. The treatment by massage must be recognised, and concerning active and passive movements he considered that active movements should be commenced earlier than was usually done and carried out more vigorously.

Mr. ROBERT JONES (Liverpool) urged that stress ought to be laid on the fact that the perfect results of treatment of fractures of long bones talked of in past times could not in reality be expected. He thought that the public needed education in regard to the fallacies of radiography. The public also ought to be taught that bones might be in a bad position with a good functional result from treatment after fracture, and that it was possible after treatment of a fracture to have the bone in good position and yet with a bad functional result. He agreed with Mr. Pearce Gould in regard to treatment by active movement.

Mr. W. ARBUTHNOT LANE said that he was unable to agree with the views expressed by the speakers who had preceded him as he considered it was the business of surgeons to do their work thoroughly in the treatment of fractures. The x rays and the law courts would in the future make surgeons more thorough in their treatment of fractures. That was a condition of things that of necessity would have to come to pass. Mr. Lane then proceeded to place before the society skiagrams of about 30 cases of fracture, in each case showing the condition before and the condition after treatment by operation. The first few cases exemplified the operative treatment of simple fractures and the remainder demonstrated instances of failure in the treatment of fractures by splints, massage, and passive and active movements whereby the necessity had arisen for operative interference. He exhibited the skiagram of a bad ununited fracture of the femur which he termed the barometer of the surgery of the present day, for the patient was informed by most leading surgeons that operation was impossible.

Mr. W. G. SPENCER said that in fractures of the long bones callus was largely formed from the periosteum and in cases where operative treatment was resorted to it had been shown that atrophy took place in the bone within the grasp of an encircling wire or along screws or plates. By reason of the callus in the long bones in the case of a fracture being so largely periosteal in its origin there was not the necessity for extremely exact and precise apposition of the fragments. Unless in exceptional cases, he could not agree that recent fractures in the shaft of long bones ought to be treated by operation, for why should a foreign body be inserted into the bone if the two ends of the bone could be placed in apposition and kept there.

Mr. C. R. B. KEETLEY referred to a paper which he had read before the society on the prevention of shortening and other forms of malunion after fracture by the use of metal pins.

Mr. J. LYNN THOMAS commented on cases of fracture in which he had seen disastrous results occur from operative treatment. He did not consider that anyone should operate on any case of fracture unless there was a certainty that non-operative treatment would not be satisfactory.

After Dr. J. SILLONVILLE had remarked that the attention of the meeting had not been called to the question of extension in the treatment of fracture of the femur, Mr. PEARCE GOULD replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Mendelism and Disease.—Exhibition of Specimens.

A MEETING of this society was held on March 6th, Dr. J. ALLAN being in the chair.

Mr. A. S. F. GRÜNBAUM read a paper entitled "Mendelism and Disease." After giving a short account of the life of Mendel and the principal experimental and other facts already ascertained concerning his laws of heredity he proceeded to put forward hypotheses to explain, along the lines of Mendel's theory, immunity and susceptibility and to account for the formation and characteristics of new growths. Where immunity depended on two factors—amboceptor and complement—such immunity would be absent unless each factor were present and in this way an immune individual might arise from two susceptible units. Apart from this, there was no justification for regarding a negative quality like susceptibility as a Mendelian characteristic. Assuming that new growths originated from the conjugation of an epithelial cell with a leucocyte or some similar combination, the offspring might be either a sarcoma or a carcinoma according to the dominant factor, or might remain a benign growth. He emphasised the necessity for complete records of both normal and abnormal members of families if their cases were to be made available for investigation along Mendelian lines.

Mr. R. LAWFORD KNAGGS and Dr. O. C. GRUNER gave a lantern demonstration on a case of Sarcoma of the Femur.

until the introduction of Bang's, which he now preferred as more trustworthy.

Lieutenant-Colonel **LEISHMAN** showed a series of microscopical specimens illustrating some points in connexion with the Parasites of Malaria. The majority of these specimens were taken from the blood or internal organs of fatal cases of malignant tertian and demonstrated the intensity of the infection in such cases. In the comatose form of this disease it was remarkable that the parasites found in the infected cells in the capillaries of the brain were, almost without exception, segmenting forms; crescents were hardly ever seen. A similar condition was seen in the kidneys, of which a section was also shown. After describing the specimens he pointed out the morphological differences which he had noticed in parasites of this form of malaria received from various parts of the tropics, and said that these appeared to him to support the views of those who considered that there was more than one species of malignant tertian parasite. Specimens of benign tertian and quartan parasites were demonstrated, as well as a case of mixed infection with all three forms. The possibility of the occurrence of parthenogenesis in benign tertian was then discussed; Lieutenant-Colonel Leishman had never encountered forms such as those described by Schaudinn under the name of "gameto-schizonts" but he showed an example of a cell apparently infected by two parasites, one a rosette and the other a gamete, which appeared to him to afford a possible explanation of the forms figured by Schaudinn. Lieutenant-Colonel Leishman further demonstrated living specimens of the flagellated forms of the parasite of kala-azar from a culture on Novy and McNeal's medium which he had received from M. Nicolle of the Pasteur Institute, Tunis.

Captain J. O. **KENNEDY**. R.A.M.C., read a paper entitled an Encysted Nematode (Œsophagostoma Inflatum) occurring in the Intestines of Monkeys (Macacus Rhesus) and causing Septic Peritonitis, and illustrated it with specimens and photographs of the infected parts and of the nematode, its embryo and eggs. The disease was characterised by the presence of cysts containing a sexually developed worm, which had a constant relationship to the longitudinal muscular bands of the cæcum and colon. He explained the origin and the various positions, of the cysts thus: the embryo gaining admission to the blood stream lodges in the longitudinal muscular band and causes a slight hæmorrhage which can be seen through the peritoneum as a thin streak in the long axis of the muscle. Here the cyst is developed and as it grows becomes too large to be contained in the muscle; it is therefore squeezed inwards to lie in the submucosa or outwards to become surrounded by peritoneum. Lying in the peritoneal cavity it becomes adherent to adjacent structures such as the omentum. Finally, the worm ruptures the cyst and a local abscess or a general septic peritonitis is produced. He had not been able to find that such a condition had been previously described.

OTOLOGICAL SECTION.

Clinical Cases.—Exhibition of Specimens.

A MEETING of this section was held on March 7th, Dr. PETER MCBRIDE being in the chair.

Mr. H. H. B. **CUNNINGHAM** showed two cases of Deafness resulting from Epidemic Cerebro-spinal Meningitis.—In the opinion of the meeting nothing could be done for these cases but as a prophylactic measure lumbar puncture was suggested.

Dr. **ADOLPH BRONNER** read notes of a case of Purulent Otitis Media with Deep Ulceration of the External Meatus occurring in Secondary Syphilis and laid stress on the fact that purulent otitis media is very rare in such conditions. Under anti-syphilitic and local treatment the symptoms soon cleared up.

Dr. D. R. **PATERSON** described an interesting case of Crossed Abducens Paralysis occurring in the course of a Cerebellar Abscess. As a result of operation the patient made an uninterrupted recovery. No opinion was expressed with regard to the causation of the ocular paralysis.

Mr. C. H. **FAGGE** read notes of a case of a Branchial Sinus leading from the Neck into the External Auditory Meatus. The sinus was excised by operation with complete success.

Dr. W. **MILLIGAN** described a case of Epithelioma of the Middle-ear of possible Traumatic Origin the result of a blow received nine months previously. The mastoid was opened on account of the severe pain. The patient afterwards died and a large intracranial abscess involving the temporo-sphenoidal lobe was discovered at the post-mortem examination.

Mr. P. **MACLEOD YEARSLEY** showed a case of Labyrinthine Suppuration in a boy, aged eight years, the result of measles when one year old. The condition was discovered whilst performing the complete mastoid operation, there being no previous symptoms pointing to labyrinthine disease. The vestibule was laid open by removal of bone below the fenestra ovalis. There was an uneventful recovery.

Dr. **ALBERT GRAY** exhibited specimens and photographs of pathological conditions found in the labyrinth, and Mr. **SYDNEY SCOTT** histological preparations of the human labyrinth.—These preparations were greatly appreciated and admired by members of the section.

An instructive and interesting paper was communicated by Mr. C. E. **WEST** and Mr. **SCOTT** on the Operative Surgery of Labyrinthitis based upon an experience of 30 cases, of which 26 cases were operated upon. The paper was illustrated by specimens of the temporal bone prepared by Mr. West.—A useful discussion resulted in which members expressed varying opinions with regard to the indications for, and methods of, operating on the labyrinth.

MEDICAL SOCIETY OF LONDON.

Discussion on the Diagnosis and Treatment of Fractures of Long Bones.

A MEETING of this society was held on March 9th, Dr. J. KINGSTON FOWLER, the President, being in the chair.

Mr. A. **PEARCE GOULD**, in opening a discussion on the Diagnosis and Treatment of Fractures of Long Bones, stated that his intention was to suggest certain points on which professional opinion was not yet decided, with the hope that many surgeons would express their opinions on these points. The well-recognised and classical signs of fracture—suddenly produced deformity, localised pain and tenderness, and oftentimes mobility in the length of the bone, with crepitus—were sufficient to lead to the recognition of the great majority of fractures, and the introduction of other means, particularly skiagraphy, should not lessen the thoroughness of the investigation of these older symptoms of fracture. He emphasised the great value of anæsthesia, both in arriving at a correct diagnosis and in applying proper treatment to a recent fracture. By the use of the x rays a fracture could be demonstrated when by other means it would only be suspected and in some cases where even the surgeon had not even previously suspected it. But in such cases it was possible to take the position that the recognition of the fracture had little or no bearing upon the prognosis of the case or upon the treatment. He referred, for instance, to fractures of the carpal bones, to incomplete fissures in long bones, and simple fissured fractures of the vault of the skull. He laid more stress upon the value of the x rays in showing the exact condition of a fracture and referred to the fact that even serious displacement in fractures of long bones might be concealed by the supervening swelling. He submitted that the importance of obtaining really accurate and complete knowledge of the details of a fracture by skiagraphy was one of the questions upon which professional opinion was not yet formed, and in

The symptoms improved and the patient lived for two months, ultimately dying from inability to take food, for which he had a total dislike from the date of admission. The specimens exhibited showed an immense blood clot in the right pleural sac. The lung itself did not appear to be affected by any tuberculous formation. The upper surface of the liver and the lower surface of the diaphragm were affected by tuberculous disease and the peritoneum was also the seat of diffuse tuberculous trouble.

Professor A. H. White exhibited a specimen of Gangrene of the Lung obtained about six years ago. The patient was a child suffering from diphtheria. The gangrenous mass was in the right lung; the destruction was quite localised and there was a considerable amount of fibrinous pleurisy. Corresponding to the centre of the gangrenous area and directly facing it was a puncture and outside, between two ribs, the puncture mark was seen surrounded by a dark blue zone. The child had apparently been inoculated with antitoxin at that point directly into the lung and this seemed to be the cause of the gangrene. The gangrenous area was found on examination to contain diphtheria bacilli, amongst other organisms, and efforts to cultivate the organism from other parts of the lung failed. Pure cultures of diphtheria bacilli were also got from the spleen. It was possible, though improbable, that the diphtheria bacilli got there by means of the serum.—Dr. John M. Day said that the patient was a boy, aged five years, who came into hospital in January, 1902. He had ordinary diphtheria and was injected with 4000 units before admission. About two days after admission he presented symptoms of pneumonia, which, however, disappeared. He then developed great fœtor of the breath and the case was diagnosed as gangrene.

Mr. K. E. L. G. Gunn exhibited five specimens of Acquired Diverticula of the Urinary Bladder. He said that congenital diverticula might occur in a very young bladder but he had never seen a congenital case. Acquired diverticula commonly occurred in the aged and were due to (1) increased *pressure*; (2) chronic inflammation of the bladder wall; *or* (3) diminished blood-supply occurring from arterial sclerosis. These diverticula went through three stages; in the *first* place some obstruction took place and the bladder became hypertrophied in order to drive the urine out. With the increase in the thickness of the muscle covering the bladder wall, fasciculation in the inner wall occurred, *followed* by a certain amount of atrophy of the muscle. The bladder then commenced to dilate and to thin out in places. Then a bulging occurred between the inner muscular fibres and the mucous membrane protruded, and so a diverticulum was formed.

Liverpool Medical Institution.—A meeting of the Pathological Section of this society was held on March 5th.—Dr. H. Leith Murray read a note on a Method of Standardising Vaccines. He uses the Thoma-Zeiss hæmocytometer, the diluting fluid being 5 per cent. Giemsa stain in 0·1 per cent. saline solution. This is filtered twice, sterilised, and 4 per cent. of formalin is added. The low specific gravity allows the organisms to sink to the bottom, the trace of salt permits of better staining, and the formalin rapidly arrests movement. The cell is covered in by a thin cover-slip chosen in the following way. A series of slips is cleaned, dried, and applied successively to the cleaned and dried plate-glass slip provided with the apparatus after breathing on the opposing face of each. Pressure is applied to make them adhere and the slips which show Newton's rings well distributed over the surface are selected for use. Counting with $\frac{1}{12}$th oil immersion is begun half an hour after placing the drop. Excess of oil is laid on and the condenser is lightly depressed. The lightly stained organisms are found lying practically motionless at the bottom, but it is advisable to focus throughout the depth of each square to detect any stragglers still floating. Three or four sets of 16 squares can be counted easily in from 15 to 20 minutes. The totals of each set of 16 show a conformity which would indicate that the lack of mathematical flatness, the cover-slip, and the possibility of slight cupping from surface tension are negligible quantities. Controls have amply confirmed the method. Using a red corpuscle pipette and taking vaccine up to the second cross-marking (i.e., a dilution of 1 in 500) the average per small square is only five organisms in a vaccine containing 10,000,000 per cubic millimetre. By using the full dilution of 1 in 1000 it would be possible to bring within range a vaccine containing 200,000,000 per cubic millimetre.—Dr. W. B. Warrington showed: (1) A specimen *considered* to be Acute Primary Infective Laryngitis occurring in a man, aged 53 years, a tailor's assistant. Death resulted from gangrenous bronchopneumonia. No etiology *or source* of infection could be traced. 2. A specimen of Thrombosis of the Aorta and Iliac Arteries *from* a *man* suffering from Septic Endocarditis. The cause of the thrombosis was considered to be infective endarteritis.—Mr. R. W. Murray showed a section of Columnar-Celled Carcinoma removed from the parietal bone of a lady, aged 60 years. The tumour had been mistaken for a sebaceous cyst. It was regarded as a secondary deposit, although careful examination had failed to show evidence of a primary growth.—Dr. R. G. Wills (for Dr. Nathan Raw) showed: 1. Lungs Infiltrated with Minute Metastatic Growths secondary to *carcinoma* of the stomach from a man, aged 32 years. The patient had been in good health until *two* months before his death and had no subjective symptoms of a stomach lesion. 2. Lung showing Secondary Sarcomatous Deposits from a female, aged 22 years. Amputation through the hip-joint for sarcoma had been performed ten months previously.—Mr. W. *Thelwall Thomas* and Dr. J. S. Rowlands exhibited: (1) Section of a *Rodent* Ulcer of the Scrotum from a man, aged *36 years*; *(2)* Carcinoma of Transverse Colon excised from a woman, aged 34 years; and (3) Hypernephroma removed from a man, aged 57 years. In this case hæmaturia was absent.—Dr. R. E. Kelly showed a case of Congenital Cleft in the Sternum in a woman, aged 28 years. The cleft involved the manubrium and first part of the meso-sternum. The cleft was V-shaped and about two inches wide above. Her only child had a perfectly normal sternum.—Dr. J. H. Stansfield showed an Omphalositic Monster, the head and upper limbs being absent and the lower limbs ended in fin-like processes. Along with the monster was born a weakly but living child with a supernumerary digit on the left hand. This was the woman's sixth pregnancy but only the eldest child had survived.—Dr. E. E. Glynn read a note on Rapid Section Cutting as an Aid to Diagnosis. The method employed was that of Dr. Louis Wilson, of St. Mary's Hospital, Rochester, Minn., U.S.A. Pieces of tissue without any preliminary fixation were frozen with ether, cut on a Cathcart microtome, floated out in 1 per cent. salt solution, stained in polychrome methylene blue, washed, and mounted in Brun's glucose medium. The epithelial and sarcomatous cells stained blue and connective tissue pink. An opinion could be given within five minutes of receiving the specimen. The method had been used in ten instances. In none had the opinion formed regarding the malignancy of the tumour been misleading.—The notes and specimens were discussed by Dr. Glynn, Dr. Warrington, Dr. J. Lloyd Roberts, Dr. F. H. Barendt, Dr. J. Hay, Mr. Thelwall Thomas, Mr. D. Douglas-Crawford, and Mr. Murray.

Hunterian Society.—A meeting of this society was held on Feb. 26th, Mr. F. Rowland Humphreys, the President, being in the chair.—Dr. A. Butler Harris read a paper on Treatment by Bacterial Vaccines. He defined a bacterial vaccine as a standardised emulsion of the dead micro-organisms in saline solution, in contra-distinction to the antitoxic sera. He referred to Wright's views on sera and the method of obtaining them. The parallels of artificial and self-induced immunisation were discussed, with special reference to the use of minimal doses of specific bacterial vaccines when inoculation was exploited. The necessity for employing vaccines obtained from cultures of the particular organism infecting the individual was emphasised. In the case of pneumococcus infection of the lung, and coli infections of the bladder and other organs, this procedure was particularly insisted on. Dr. Harris alluded to four cases of pneumonia under his care in which bacterial inoculation had undoubtedly produced an artificial crisis with recovery. A case of endocardial infection by the streptococcus which was characterised by periodic attacks with a corresponding variation of the opsonic curve was described. In this case the streptococcus was isolated from the blood and a vaccine was made and successfully employed. Dr. Harris pointed out the clinical conditions which favoured *or* hindered improvement under bacterial inoculation. He stated that one of the chief factors in retarding recovery was tissue destruction combined with the laying down of fibrous *tissue*. These conditions militated against the flooding of the infected areas with blood rich in antibacterial substances. He instanced these phenomena by comparing the conditions *in tuberculous* with those in pneumococcic infection of the lung. The congestion and non-destruction of tissue in pneumonia were favourable to a rapid immunisa*tion*. Following the argument he instanced

Lieutenant-Colonel **LEISHMAN** showed a series of microscopical specimens illustrating some points in connexion with the Parasites of Malaria. The majority of these specimens were taken from the blood or internal organs of fatal cases of malignant tertian and demonstrated the intensity of the infection in such cases. In the comatose form of this disease it was remarkable that the parasites found in the infected cells in the capillaries of the brain were, almost without exception, segmenting forms; crescents were hardly ever seen. A similar condition was seen in the kidneys, of which a section was also shown. After describing the specimens he pointed out the morphological differences which he had noticed in parasites of this form of malaria received from various parts of the tropics, and said that these appeared to him to support the views of those who considered that there was more than one species of malignant tertian parasite. Specimens of benign tertian and quartan parasites were demonstrated, as well as a case of mixed infection with all three forms. The possibility of the occurrence of parthenogenesis in benign tertian was then discussed; Lieutenant-Colonel Leishman had never encountered forms such as those described by Schaudinn under the name of "gameto-schizonts" but he showed an example of a cell apparently infected by two parasites, one a rosette and the other a gamete, which appeared to him to afford a possible explanation of the forms figured by Schaudinn. Lieutenant-Colonel Leishman further demonstrated living specimens of the flagellated forms of the parasite of kala-azar from a culture on Novy and McNeal's medium which he had received from M. Nicolle of the Pasteur Institute, Tunis.

Captain J. C. **KENNEDY**, R.A.M.C., read a paper entitled an Encysted Nematode (Œsophagostoma Inflatum) occurring in the Intestines of Monkeys (Macacus Rhesus) and causing Septic Peritonitis, and illustrated it with specimens and photographs of the infected parts and of the nematode, its embryo and eggs. The disease was characterised by the presence of cysts containing a sexually developed worm, which had a constant relationship to the longitudinal muscular bands of the cæcum and colon. He explained the origin and the various positions, of the cysts thus: the embryo gaining admission to the blood stream lodges in the longitudinal muscular band and causes a slight hæmorrhage which can be seen through the peritoneum as a thin streak in the long axis of the muscle. Here the cyst is developed and as it grows becomes too large to be contained in the muscle; it is therefore squeezed inwards to lie in the submucosa or outwards to become surrounded by peritoneum. Lying in the peritoneal cavity it becomes adherent to adjacent structures such as the omentum. Finally, the worm ruptures the cyst and a local abscess or a general septic peritonitis is produced. He had not been able to find that such a condition had been previously described.

OTOLOGICAL SECTION.

Clinical Cases.—Exhibition of Specimens.

A MEETING of this section was held on March 7th, Dr. PETER McBRIDE being in the chair.

Mr. H. H. B. **CUNNINGHAM** showed two cases of Deafness resulting from Epidemic Cerebro-spinal Meningitis.—In the opinion of the meeting nothing could be done for these cases but as a prophylactic measure lumbar puncture was suggested.

Dr. **ADOLPH BRONNER** read notes of a case of Purulent Otitis Media with Deep Ulceration of the External Meatus occurring in Secondary Syphilis and laid stress on the fact that purulent otitis media is very rare in such conditions. Under anti-syphilitic and local treatment the symptoms soon cleared up.

Dr. D. R. **PATERSON** described an interesting case of Crossed Abducens Paralysis occurring in the course of a Cerebellar Abscess. As a result of operation the patient made an uninterrupted recovery. No opinion was expressed with regard to the causation of the ocular paralysis.

Mr. C. H. **FAGGE** read notes of a case of a Branchial Sinus leading from the Neck into the External Auditory Meatus. The sinus was excised by operation with complete success.

Dr. W. **MILLIGAN** described a case of Epithelioma of the Middle-ear of possible Traumatic Origin the result of a blow received nine months previously. The mastoid was opened on account of the severe pain. The patient afterwards died and a large intracranial abscess involving the temporo-sphenoidal lobe was discovered at the post-mortem examination.

Mr. P. **MACLEOD YEARSLEY** showed a case of Labyrinthine Suppuration in a boy, aged eight years, the result of measles when one year old. The condition was discovered whilst performing the complete mastoid operation, there being no previous symptoms pointing to labyrinthine disease. The vestibule was laid open by removal of bone below the fenestra ovalis. There was an uneventful recovery.

Dr. **ALBERT GRAY** exhibited specimens and photographs of pathological conditions found in the labyrinth, and Mr. **SYDNEY SCOTT** histological preparations of the human labyrinth.—These preparations were greatly appreciated and admired by members of the section.

An instructive and interesting paper was communicated by Mr. C. E. **WEST** and Mr. **SCOTT** on the Operative Surgery of Labyrinthitis based upon an experience of 30 cases, of which 26 cases were operated upon. The paper was illustrated by specimens of the temporal bone prepared by Mr. West.—A useful discussion resulted in which members expressed varying opinions with regard to the indications for, and methods of, operating on the labyrinth.

MEDICAL SOCIETY OF LONDON.

Discussion on the Diagnosis and Treatment of Fractures of Long Bones.

A MEETING of this society was held on March 9th, Dr. J. KINGSTON FOWLER, the President, being in the chair.

Mr. A. **PEARCE GOULD**, in opening a discussion on the Diagnosis and Treatment of Fractures of Long Bones, stated that his intention was to suggest certain points on which professional opinion was not yet decided, with the hope that many surgeons would express their opinions on these points. The well-recognised and classical signs of fracture—suddenly produced deformity, localised pain and tenderness, and oftentimes mobility in the length of the bone, with crepitus—were sufficient to lead to the recognition of the great majority of fractures, and the introduction of other means, particularly skiagraphy, should not lessen the thoroughness of the investigation of these older symptoms of fracture. He emphasised the great value of anæsthesia, both in arriving at a correct diagnosis and in applying proper treatment to a recent fracture. By the use of the x rays a fracture could be demonstrated when by other means it would only be suspected and in some cases where even the surgeon had not even previously suspected it. But in such cases it was possible to take the position that the recognition of the fracture had little or no bearing upon the prognosis of the case or upon the treatment. He referred, for instance, to fractures of the carpal bones, to incomplete fissures in long bones, and simple fissured fractures of the vault of the skull. He laid more stress upon the value of the x rays in showing the exact condition of a fracture and referred to the fact that even serious displacement in fractures of long bones might be concealed by the supervening swelling. He submitted that the importance of obtaining really accurate and complete knowledge of the details of a fracture by skiagraphy was one of the questions upon which professional opinion was not yet formed, and in had been working as an ordinary labourer for some time.—Dr. W. J. Maurice (Reading) read a paper entitled "A Few Notes to Illustrate the Dangers of Delay in Performing Operations." After remarking that every practical surgeon knew that his failures were mostly due to delay, either on his own part or on that of those who had been attending the case before him, or to the unwillingness of his patient to submit to operation in good time, Dr. Maurice said that he could always recall plenty of cases in which success could be attributable to little else than a prompt recognition of the needs of the case and immediate and appropriate action. The older and the more modern ways of dealing with strangulated hernia were contrasted and a case was cited showing that the old methods of vigorous taxis coupled with a certain amount of expectancy had not yet entirely died out. Dr. Maurice next related some cases in which the dangers involved in delaying operation were very manifest—a case of pyloric obstruction being the first example given. Three cases of twisted ovarian pedicle were next detailed; all were successful but in each instance it was evident that delay in operating would have proved fatal. A case was next related of a patient with a pelvic abscess who lost her life solely owing to the postponement of operation, the abscess which originally burst into the vagina filling again and rupturing into the peritoneum. A fatal case of strangulated bowel was also recorded in which it was conceivable that an early operation might have saved the patient. Delay in operating also appeared to be responsible for the death of a patient with ruptured intestine. Dr. Maurice concluded his paper with a few remarks on acute appendicitis which were listened to with great interest. He was of opinion that suppuration was more frequent and occurred earlier than was the case a few years ago. He said that he was in the habit of operating immediately upon any acute case that was not decidedly better at the end of 48 hours; if the pulse were quick and the symptoms generally active he would operate still earlier—as soon as the chance presented. If pus were present it could be evacuated; if not, the appendix could be removed and the patient saved further trouble. Finally, after remarking that he had often had occasion to regret the postponement of operation, Dr. Maurice said that he could not recall a single instance in which he regretted having operated.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 7th, Mr. Richard Lake, the President, being in the chair. The following specimens, amongst others, were shown.—Mr. Cecil H. Leaf: (1) Two specimens of Fibroid of the Uterus removed by Supravaginal Hysterectomy; (2) Multiple Cystic Tumour of the Thyroid removed by Operation; and (3) Carcinoma of the Rectum removed by Kraske's Method.—Mr. W. McAdam Eccles: Specimens illustrating some of the Less Common Diseases of the Testis.—Mr. J. G. Pardoe: Two specimens of Malignant Hypernephroma, and microscopical slides.—Dr. D. Arthur: X-ray Diographs.—Mr. Donald J. Armour: Goitre (Exophthalmic).—Dr. A. E. Russell: Congenital Narrowing of the Subclavian Artery, simulating Aneurysm, associated with Angina Pectoris.—Mr. F. Swinford Edwards: Enlarged Prostates.—Dr. G. P. Low: Pathological specimens—Tumour of Liver; Spine showing Erosion by Aneurysm; Intestine showing Dysenteric Ulceration; Pachymengitis Hæmorrhagica; and Aneurysm of Transverse Arch Bursting into Œsophagus.—Dr. H. Macnaughton-Jones: (1) Two specimens illustrating the Difference between Ovarian and Tubo-ovarian Blood Cysts; (2) a series illustrative of Malignant Disease of the Ovaries; (3) a series illustrative of Sclerosis and Cirrhosis of the Ovaries; (4) three specimens of Primary Tuberculosis of the Fallopian Tube; (5) four coloured plaques of the Female Pelvis (showing all the organs); (6) a skiagraph of Calculus of the Kidney with the removed Calculus; and (7) a skiagraph of the Ankle-joint showing Ankylosis (after bullet wound).—Mr. Aslett Baldwin: Horseshoe Kidney; Knee-joint showing Osteo-arthritis; section of Anthrax of Cheek due to a Flybite; and other microscopic specimens.—Mr. Ernest H. Shaw: (1) Tuberculous Tumours in the Brain of a Child; (2) Mixed Tumour of Submaxillary Salivary Gland; (3) Fibroids of Uterus, one calcified; and (4) Cystic Hæmorrhagic Carcinoma of the Breast.—Mr. C. R. B. Keetley: Malignant Growth of the Intestines.—Dr. J. H. Dauber: Uterine Fibroids.—Mr. A. C. D. Firth: Sarcoma of the Intestine.—Dr. Phineas S. Abraham: Photographs of Skin Diseases.

Reviews and Notices of Books.

Judicial Statistics, England and Wales, 1906. Part I., Criminal Statistics. London: Wyman and Sons. 1908. Pp. 203. Price 2*s.* 3*d.*

THE fourteenth volume of the new series of criminal statistics contains the usual information relating to crime and criminal proceedings during the year 1906. The figures are arranged in the same tabular form which has been followed since the revision of the statistics by the departmental committee appointed by Mr. Asquith in 1892. This year, however, the comparative tables have been carried back to 1857, the year in which the judicial statistics were first published, so that they afford a comprehensive view of the movement of crime during the past half century.

Considering first the figures for 1906, we find that the amount of serious crime during the year was lower than in 1905 and was also below the average for the period 1902-06. This decline is shown, though in somewhat different degree, by all the available measures—number of crimes reported to the police, and number of persons tried for, and number of persons convicted of, indictable offences. Of these criteria the number of persons tried for indictable crimes is usually regarded as the most trustworthy. In 1906 this number was 59,079, while in 1905 it was 61,463, and during the period 1902–06 it averaged 59,203. The decline indicated by these figures, though slight in degree, is noteworthy because it shows an arrest in the upward tendency which characterised the movement of serious crime during the seven years 1899–1905.

As has often been pointed out the statistics of crime taken as a whole are indicative simply of the amount of crimes of acquisitiveness, which constitute about four-fifths of the total delinquency in this country. They, therefore, afford no guidance as to the tendency in crimes of violence and of lust, which may, and in fact very frequently do, move in an opposite direction. This was the case in 1906, the fall in offences of acquisitiveness being accompanied by a rise in the amount of homicidal and of sexual crime. Crimes of violence increased by 8·5 per cent. and crimes of lust by 7·5 per cent. as compared with the figures for 1905. These oscillations in the several categories of delinquency in 1906 coincided with, and may presumably to some extent be attributed to, the economic conditions which prevailed during the year. Wages in 1906 showed a net increase for the first time since 1900. The percentage of unemployed amongst members of trade unions was the lowest recorded since 1901. The general level of wholesale prices was higher than for the preceding 16 years, while there was at the same time a perceptible decline in the prices of food and drink. The total of imports and exports and the total sum dealt with at the London Clearing House showed considerable increase. There was a slight decline in pauperism. The year, therefore, was emphatically one of general prosperity, and it is, of course, the rule that in such years thefts diminish while crimes of violence and of lust and drunkenness increase.

While 1906 conformed fully to this rule as regards the several varieties of serious crime, it is remarkable that despite the increase in homicidal and sexual offences there was a fall in the number of assaults tried summarily and in the number of prosecutions for drunkenness, the decrease under each head amounting to about 3 per cent. on the figures for the preceding year. The explanation of this fact is probably to be sought rather in a slackening of police activity than in any change in popular manners calculated to sever the regular association of good times with increased drunkenness. Several points which appear on a closer scrutiny of the

Dr. Gruner showed microscopical preparations from cases of Gastritis Hyperplastica Chronica in which the wall of the stomach was widely, and in some cases universally, thickened. There was absolutely no evidence of malignant disease, but histologically the tissues were densely infiltrated by inflammatory cells of all kinds and more especially plasma cells. The causation of the condition was not known, though the clinical features resembled those of chronic dyspepsia. There was almost complete absence of the gastric glands. So far six cases had been met with during five years at the Leeds General Infirmary. A specimen was shown illustrating the presence of peculiar "islands" (very similar to those of the pancreas) in the adrenal medulla. They were found with some frequency in 150 consecutive post-mortem examinations and only after childhood. The condition seemed so far to have passed unnoticed.

Mr. Alexander Sharp showed a specimen of Exostosis of the External Auditory Meatus in a patient aged 30 years. The left ear had been almost completely deaf for seven years and during the same period there had been intense neuralgic pain involving the left side of the face and head. On examining the ear there was seen a pale pink bony growth, with smooth surface, which completely filled the meatus; it was excessively tender and there was a history of repeated attacks of inflammation. The growth was found to be attached to the antero-superior meatal wall and was removed with hammer and gouge by way of the meatus. Since the operation the headaches had disappeared and the hearing had become quite normal.

Mr. B. G. A. Moynihan showed a specimen of Acute Phlegmonous Gastritis. The condition was diagnosed at an exploratory laparotomy. Death occurred on the next day. The stomach was removed through the operation wound. After removal a pure culture of bacillus coli was obtained from the cut surface. The submucous coat was distended with a grey sloughy material from the cardia to the pylorus, consisting chiefly of leucocytes. The mucosa was normal. The muscular coat was somewhat infiltrated with leucocytes. Microscopically diplococci and short wide bacilli, probably sporing organisms, were found.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of State Medicine.

Alcohol and Mental Disease.

A meeting of this section was held on Feb. 14th, Dr. W. R. Dawson, the President, being in the chair.

The President said that his paper was intended merely as a contribution to a general discussion on alcohol. Apart from personal predilections, the uncertainty existing with reference to the effects of that drug was largely due to deficient appreciation of the influence of individual diathesis and of the varying effects of different doses. With normal individuals, in appropriate circumstances, small doses properly diluted, taken with food and not too frequently, were physiologically beneficial. With larger doses the matter was otherwise. A drunken bout was not only a microcosm of insanity but indicated the probable course of chronic alcoholism in the same individual. Different persons showed different symptoms. When alcohol was taken more continuously, though in small doses, the same order of degradation was observed, the "high level" moral and other late-acquired qualities being first affected, then the motor and sensory functions, and, lastly, those of mere nutrition. A complete estimate of the relation of mental disease to alcohol was impossible. Of asylum cases the prevailing opinion seemed to be that from 15 to 20 per cent. were due to alcohol, but this estimate was almost certainly too high. The regional distribution of insanity did not correspond with that of either alcoholism or drunkenness, and it seemed probable that not more than 10 per cent. of the asylum cases were genuinely attributable to alcohol. The cases in which alcohol was merely contributory must be numerous, owing to the susceptibility to alcohol of persons with any hereditary or acquired brain weakness. Though there was the strongest evidence of the evil effects of parental alcoholism upon the offspring, the question had really nothing to do with the transmissibility or otherwise of acquired characters, the phenomena being sufficiently explained by the deleterious action of the drug upon the germs of the future individual. Chronic alcoholism produced worse effects than occasional drunkenness, and bad spirits produced worse effects than pure ethyl-alcohol. As regards the forms of insanity due to alcohol, certain symptoms were suggestive of this cause—namely, impulsiveness, suspiciousness, confusion with hallucinations, loss of memory for recent events, and fabrication of imaginary occurrences. The most purely alcoholic forms were delirium tremens, Korsakoff's psychosis, hallucinatory-confusional insanity, and alcoholic dementia. Pathologically the changes in the more chronic forms were found round the fissure of Rolando affecting chiefly the large pyramids. If alcohol be cut off, the mental improvement is usually rapid, but for the habit itself compulsory prolonged total abstinence is the only cure.

The MacDermot said that he had during the past seven years as inspector of prisons visited one of the Irish prisons almost every week and had tried to make himself familiar, so far as possible, with the penal and family records of the prisoners. He had, in addition, superintended the work of the State Inebriate Reformatory at Ennis during the past four or five years. He entirely disagreed with the neo-Darwinian theory that a great number of the human species had an original taste for alcohol, a taste which, being natural, was not acquired. On the contrary, the theory of Lamarck that a taste for alcohol was an acquired habit and that acquired tastes were transmissible would give great confidence in all temperance movements.

Dr. Walter G. Smith said that their chief knowledge of the scientific effects of alcohol was a quite recent growth and he thought that the turning point was reached by Schmiedeberg who, with unanswerable arguments, demolished the view still held by many that alcohol belonged to the class of stimulants. Alcohol was an essential member of the narcotic group of substances. Most medical men were much more cautious now than in his student days about the administration of alcohol, especially in acute disease. They had learned that most diseases got on better without alcohol. To a person in health on a sufficient diet alcohol was absolutely unnecessary and possibly injurious to some people, but it was idle to deny its possible value as a food in some cases. The points which related to the public in regard to alcohol were: (1) its effects in producing visceral disease; (2) its leading to all sorts of crime; and (3) its influence on the nervous tissue. The last was a very complicated question but there could be no doubt as to the deleterious effects of long-continued doses of alcohol on the brain.

Dr. Thomas Donnelly said that a great responsibility rested with the medical profession and a great deal of good was now being done through the agency of the profession in putting before the people the physiological action of alcohol and the deleterious effects of over-indulgence. It was exceedingly unwise of physicians to permit alcohol as a beverage without marked restrictions as to its discontinuance after a time. It should not be prescribed in any respect except as a drug and in his opinion should never be given to mothers who were suckling their infants.

Mr. O'Connell J. Delahoyde, who confessed himself a lifelong total abstainer, having never tasted any liquor that was brewed or distilled, said that statistics did not fully represent the amount of insanity which was directly traceable to alcohol. He on occasions prescribed alcohol, but always under strict conditions.

Dr. Ninian Falkiner, Mr. G. R. S. Stritch, Dr. Henry T. Bewley, and Dr. William A. Winter also took part in the discussion.

Section of Pathology.

Exhibition of Specimens.

A meeting of this section was held on Feb. 21st, Dr. A. R. Parsons the President, being in the chair.

Dr James Little, in describing an Exceptional Case of Tuberculosis, said that the patient, a man about 42 years of age, was admitted to a hospital in November, 1907, looking very emaciated. He had only a cough, with a little pain in the right side of his chest. A few days after admission a friction sound was noticed low down on the right side of the chest. His sputum did not give any tubercle bacilli. He complained of abdominal pain; he was always constipated and his temperature was hectic, though not highly so, up to his death on Feb. 8th. About a fortnight after admission it became plain that there was fluid in the right thoracic cavity and after some time 20 ounces of exceedingly bloody fluid were drawn off.

in alphabetical order, an innovation which certainly has much to commend it. As comparison with the well-known and valuable Medical Directory published by Messrs. J. and A. Churchill is inevitable, we may say at once that we do not consider that either work will interfere with the other. Nisbet's Directory is compiled on an original plan and if its future issues are kept up to the present standard success may be safely anticipated for it. It does not take the place of Churchill's Directory, giving deliberately so much less information, but it is an extremely useful alphabetical list of the profession.

The Romance of Medicine. By RONALD CAMPBELL MACFIE, M.A., M.B., C.M. Aberd. London: Cassell and Co. 1907. Pp. 312. Price 6*s.* net.

THE author of this book has evidently been at some pains in its writing and we can fully credit his claim to have consulted 300 volumes in the process. The result is a *pot-pourri* of popular science and of medical history, presented with a certain smartness which at times gets a little out of hand. Thus: "Hitherto man had dared to consider himself a little lower than the angels, now he might venture to consider himself a little higher than the amœbæ. Now might he say to the worm, 'Thou art my brother and my sister,' and to the tubercle bacillus, 'Thou art my brother Cain.'" And again: "We read in the first chapter of Genesis how, when God made Eve from one of Adam's ribs, He anæsthetised Adam before the operation"; and we could extend our illustrations of the point. On the other hand, he can turn a phrase prettily and pointedly, as thus: "Lister succeeded because his surgical methods were the fruit at once of science and of art." Again, he sometimes writes loosely in his desire for effect. "The civilised consumptive has merely to cough to kill," which is a somewhat mischievous statement; and "At the time when appendicitis was in fashion most fashionable people had their appendices removed." We think that Dr. Macfie's view of Aristotle is somewhat unfair, and on p. 43 he uses the word "dogma" as if it meant "*unsound* opinion" instead of merely "opinion." However, here he is in accord with one school of modern "educationists." All this is a pity, because Dr. Macfie has very evident appreciation of his subject, the inherent romance of the progress of medical knowledge and its beneficent results to the human race, and in some measure he has succeeded in showing it forth. Thus the chapters in which he describes such discoveries as those of the circulation of the blood, the pathogenic rôle of anopheles and stegomyia, and the anæsthetic properties of nitrous oxide, ether, and chloroform must needs compel in their readers an added respect for the science of medicine. The history of anæsthesia is especially well narrated, as is the deathless story of Pasteur's victory over hydrophobia. In telling this Dr. Macfie has drawn freely upon Vallery-Radot's enthralling biography of his revered master, and the inclusion of the beautiful story of Pasteur's dealings with his little Alsatian patient Meister in these pages may perchance turn the heart of some bigot who persistently denies the bare possibility of any humane feelings in an apostle of pathological research. These chapters, which show the substance of true romance, will probably have much more value for the general reader than those in which he is told of serums, opsonins, side-chains, and the like, of which he could gain only the faintest conception from these pages. Still less to our taste is the last chapter, with its summary of the more sensational aspect of modern surgery, its text-book description of a case of myxœdema, and other matters which we regret that the author has addressed to the general public. There is much matter, however, in the volume to interest most people legitimately and medical men who have scant leisure for the study of the archives of their mystery will find a good store of delightful knowledge in its pages. Of this we may further instance the author's accounts of the well-nigh Sybilline prevision of many of the greatest discoveries in medicine, which has not seldom been possessed by men living even centuries before the advent of the master who should reveal them fully, as witness the writings of Cesalpinus, Bassi, and Place, who each in his day respectively foreshadowed the great work of Harvey, Pasteur, and Lister. And Dr. Macfie provides other food for deep reflection in his pages. We thank him especially for his spirited version of the story of Simpson's chloroform party.

Diseases of the Stomach. By Dr. I. BOAS, Specialist in Gastro-Enteric Diseases in Berlin. The sole authorised English-American edition from the latest German edition. By ALBERT BERNHEIM, M.D. Freiburg, Assistant to the late Dr. D. D. Stewart at the Polyclinic Hospital and Post-Graduate School as Instructor in the Department of Diseases of the Stomach, &c. Philadelphia: F. A. Davis Company. 1907. Pp. 730. Price $7 net.

THE first part of this work, after a voluminous series of prefaces, is devoted to an account of methods of examination and to a general review of the therapeutic procedures which are applicable to diseases of the stomach. The second part deals with gastric disorders *seriatim*, both organic and functional. The account given is very full and explicit; indeed, Dr. Boas's reputation is sufficient guarantee that the matter of the book is satisfactory. The translator from time to time adds notes derived from his own experience and that of other American writers, which are incorporated in the text. In one place no less than ten pages are quoted verbatim from Dr. Hemmeter's book on Diseases of the Stomach. The translation possesses about the degree of merit commonly found in American translations. It would have been expected that in a population in which so large a German element was present it would be easy to find translators having a competent knowledge of both English and German. Yet it is quite the exception to find a translated work in which it is possible for a minute to forget that we are not studying an original production. We may quote such sentences as the following, the italics being in every case our own: "Other *forms* of artificial feeding have not been *naturalised* in the treatment of gastric ulcer"; "a source of mistaken diagnosis *rests* in the fact ......"; (cancer) "begins gradually to *slide from old age to the strongest middle life*"; "an *aspirable* object"; (œdema) "is, therefore, if present at all, likewise but a *sustaining* symptom"; and the "*rash* occurrence of cancer." We venture to doubt whether such expressions can be justified even as characteristic of the American dialect; they cannot be called English. Fortunately, *as a rule*, the text of the book is intelligible, if not elegant, and the translation may be of use to those who desire to study Dr. Boas's valuable writings but who cannot master the original German.

LIBRARY TABLE.

Diagnostik der Bewegungsstörungen der Augen. (Diagnosis of the Disorders of Mobility of the Eyes.) By Dr. Med. E. LANDOLT, of Paris. With one plate and 23 figures in the text. Leipsic: W. Engelmann. 1907. Pp. 94. Price 3 marks 60 pfennigs.—Dr. Landolt must find it an easy and a congenial task to write an elementary introduction to the study of the ocular muscles. He has already written the articles on this subject in the now almost obsolete French treatise of de Wecker and Landolt and in the new edition of the great German treatise of Graefe and Saemisch. The present brochure contains nothing new and is purely elementary in its scope. It is characterised by the lucidity which we are accustomed to expect from French writers in general and from Dr. Landolt in particular. After dealing very briefly with the anatomy and physiology of the ocular the help von Bier's method had proved in inducing a better supply of blood to the infected areas. He urged the adoption of free surgical interference in chronic abscesses and sinuses, followed or even preceded by the employment of an appropriate bacterial vaccine. The signal results obtained by the use of minimal doses of tuberculin in the early glandular infections of young children were alluded to. After illustrating the effect of bacterial inoculation in various staphylococcic infections of the skin by cases which had come under his own observation, he remarked that he considered the employment of vaccines was but a link in the chain of general treatment, of which medicine was at one end and surgery was at the other.—Mr. James MacMunn read a paper on the Modern Treatment of Diseases of the Lower Urinary Tract. He said that radical cure of stricture of the urethra would more often follow internal and external urethrotomy if the anatomy of stricture were borne in mind and the after-treatment were somewhat different. In internal urethrotomy the stricture should not only be well divided but the edges of the wound should be kept apart and artificially varnished till covered by epithelium, irritation being avoided. In external urethrotomy failure often arose from the agglomeration of the cellulo-cutaneous cicatrix with that in the urethra, forming a larger contractile mass. In some cases making the superficial cut to one side of the middle line was therefore advocated. Dilatation was usually much more efficient if followed by the pressure of a bottle of hot water to the perineum. It could be done when the patient retired. In urethritis avoidance of hyperæmia was the first indication. He suggested that the bulb of the urethra was a pouch for semen before the latter was finally expelled and that it might be styled the ampulla urethralis seminis.—Dr. A. W. Wakefield gave a demonstration on the Employment of Bier's Method of Congestion for cases of sepsis, mastitis, tubercle, gout, gonorrhœal arthritis, &c. The bandage method with modifications for the shoulder and digits was shown. Then the suction apparatus was explained and its many modifications, including the simple means by which an ordinary douche glass, a piece of rubber sheeting, a Sprengel pump, and some rubber tubing might be fixed up to form an efficient suction apparatus at the cost of a few shillings only. Emphasis was laid on the simple and almost the only rule of Professor Bier, that congestion must relieve and not cause pain. Bier was also of opinion, and in this was supported by nearly all authorities on the subject, that in the case of tubercle congestion should not be maintained for more than an hour daily. Brief allusion was made to the extraordinary results achieved in many cases by this treatment.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on March 6th, Dr. W. Langdon Brown, the President, being in the chair.—Dr. T. Grainger Stewart read a paper on Vascular Lesions of the Nervous System. He described the pathogenesis of the various forms of vascular lesion and the pathological changes which result from (1) a partial cutting off of the blood-supply without softening; (2) complete occlusion of a cerebral vessel; and (3) rupture of a cerebral vessel. After referring to the effects of such lesions occurring in early life and the clinical manifestations to which they gave rise, he passed on to the consideration of these lesions when occurring in the adult. Speaking of the relative frequency of thrombosis, embolism, and hæmorrhage, he pointed out that thrombotic softening was the most common lesion despite the greater frequency of hæmorrhage, as noticed in the post-mortem records of general hospitals, and that in special hospitals and in workhouse infirmaries the relative frequency was reversed. The chief vascular diseases giving rise to the production of thrombotic occlusion were (1) syphilitic endarteritis which was the common cause of thrombosis in early middle life and such cases often occurred within two or three years after the primary infection, in some cases within 12 months; and (2) atheroma which was the chief factor in cases occurring in later middle life and old age. Embolic softening was comparatively rare and usually took place during an attack of malignant endocarditis or pyæmic affection. Cerebral hæmorrhage was dependent upon two factors, the weakening of the vessel wall and a blood pressure sufficient to cause rupture of the weakened vessel. In cases of pure cerebral hæmorrhage the association of vascular disease, chronic renal disease, and hypertrophy of the left ventricle was striking, and also the fact that in these cases a sudden increase in blood pressure due to emotion or physical strain was the usual exciting cause of the stroke. In other cases, in addition to the vascular changes, weakening of the supporting perivascular tissue from previous thrombotic softening still further favoured the occurrence of hæmorrhage without any sudden increase in the blood pressure. In the records of 22 cases of cerebral hæmorrhage in 13 there was evidence of previous thrombotic lesions. After describing the clinical distinctions between the onset of thrombotic, embolic, and hæmorrhagic apoplexy he referred to the prognosis. In syphilitic thrombosis the outlook was favourable both as regards the stroke and the subsequent duration of life; in atheromatous cases the duration of life seldom exceeded three years but might be prolonged for five years, but in both forms the presence of renal disease and cardiac hypertrophy rendered the prognosis very unfavourable. In ventricular hæmorrhage death as a rule resulted within 14 hours. When the hæmorrhage was confined to the brain substance the prognosis was not so favourable as in thrombosis and the subsequent duration of life was rarely over 18 months. In meningeal hæmorrhage intradural and basal hæmorrhages were rapidly fatal, but ingravescent cases and post-traumatic cases might, if recognised early, result in complete recovery as the result of operative measures. The treatment consisted of rest and quiet and the early use of iodide of mercury in the syphilitic cases. In thrombosis the patient's vitality must not be lowered and where there was any hypertrophy of the heart cardiac stimulation must be rigorously avoided. The state of the blood pressure must be the guide in all cases, an endeavour being made to keep it at a suitable and constant level.—The President showed several organs of a man who had died from Melanotic Sarcoma which had in the first instance affected the right eye. Practically the whole of the left lung was converted into a mass of melanotic sarcoma and there were growths in the pericardium, diaphragm, pancreas, and intestines.—Dr. B. G. Morison showed a woman, aged 50 years, with extreme Chronic Rheumatoid Arthritis of both Hands and Feet.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 4th, Mr. J. Mackie being in the chair.—Dr. A. B. Dunne showed a boy, aged 11 years, from whom he had removed a Darning-needle over three inches in length, which had become imbedded in the gluteal muscles and probably penetrated the great sacrosciatic ligament.—Mr. W. Morley Willis showed a girl, aged 14 years, from whom he had removed the Breast and Axillary Contents a fortnight before for a tumour of doubtful nature (? adeno-sarcoma), microscopic sections of which were also shown.—Mr. Willis also showed a woman, aged 41 years, both of whose Breasts contained hard nodules, probably due to chronic mastitis of four years' duration, with glandular enlargement on one side.—The cases were discussed by Dr. W. Tibbles, Dr. J. Watson, Dr. A. M. Webber, Dr. J. A. O. Briggs, Mr. A. R. Tweedie, Mr. K. Black, and Dr. W. Hunter, and Mr. Willis replied.—Mr. Willis read a paper on Some Common Causes of Urinary Obstruction and their Treatment. The causes included in the male phimosis, urethral foreign bodies and calculus, urethritis, stricture, prostatic hypertrophy, and prostatic hæmorrhage, which might even distend the bladder. In the female the causes alluded to were imperforate hymen and retained menses, urethral papilloma, uterine fibroids, retroverted gravid uterus, and calculus.—The paper was discussed by Mr. Mackie, Dr. J. H. Thompson, Dr. Hunter, Dr. J. A. Waring, Dr. A. J. Sharp, Dr. A. C. Reid, Dr. Briggs, Dr. Dunne, Mr. Tweedie, and Dr. J. W. Scott, and Mr. Willis replied.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on Feb. 25th, Mr. W. A. U. Thomson (Maidenhead), the President, being in the chair.—Dr. F. J. Hathaway (Windsor) exhibited a case of Charcot's Disease of the Knee-joint. The case was one of some years' standing and there was great deformity.—Dr. S. G. Tippett (Staines) showed a man suffering from some Obscure Nervous Symptoms thought to be due to Commencing General Paralysis.—Dr. A. O'Neill (Windsor) showed a case of Aneurysmal Varix of the Hand and Arm which had existed since childhood.—Dr. E. S. Norris (Eton) showed a woman, aged 43 years, with a large Inoperable Carcinoma of the Breast.—Dr. C. R. Elgood showed a man aged 22 years, whose heart had undergone perfect Compensation after most Extensive Valvular Lesions. The patient appeared to be in excellent health and short periods of rest or of submaximal stimulation. 2. S. Jean Meiklejohn, M.B., Ch.B., Carnegie Scholar, On the Development of the Plexiform Nerve Mechanism of the Alimentary Canal. Dr. Meiklejohn employs staining methods and his results show that the visceral (Auerbach's) plexus is formed later than, and probably as an outgrowth from, the synaptic system, and not as an independent system, afterwards forming a secondary connexion with the central nervous system. 3. T. G. Brodie, M.D. Lond., F.R.S., and Winifred C. Cullis, the Analysis of Oxygen and Carbonic Acid contained in Small Volumes of Saline Solutions. 4. H. C. Bazett, Wadham College, Oxford, Observations on the Refractory Period of the Sartorius of the Frog. 5. E. W. S. Carmichael, M.B. Edin., F.R.C.S. Edin., and F. H. A. Marshall, D.Sc., on the Occurrence of Compensatory Hypertrophy in the Ovary. The experiments of the authors of the article show that hypertrophy of the one ovary does occur after removal of the opposite one. 6. P. C. Varrier-Jones, B.A., Effect of Strychnine on Muscular Work. 7. Edward Mellanby, B.A., Creatin and Creatinin. 8. J. Theodore Cash, On the Physiological Action of the Seeds of Garcia Nutans Omphalea Megacarpa and Omphalea Triandra from Trinidad. All these seeds possess a purgative action due to the oil which they contain. They all also produce diuresis. This number contains the Proceedings of the Physiological Society on Nov. 23rd, 1907, and on Jan. 25th, 1908.

The Medical Chronicle.—The November and December numbers (1907) are designed as a memorial to the late Professor Julius Dreschfeld. A short memoir of his life and a bibliography of his published works precede the original articles which fill the rest of the two numbers; of these we have only space to record the titles. Professor A. H. Young and Professor Arthur Robinson write on Malformations of the Human Heart, Mr. G. A. Wright on Some Less Familiar Joint Affections, Dr. Robert B. Wild on the Supervention of Epithelioma on Lupus Vulgaris, Dr. W. Milligan on Labyrinthine Suppuration, Dr. Ernest S. Reynolds on Intermittent Limp, Mr. F. H. Westmacott and Professor F. A. Southam on Hyperplasia of the Superior Maxilla, and Dr. Siegmund Moritz on Oral, Laryngeal, and Nasal Symptoms of Myxœdema. Mr. William Thorburn writes on the Symptoms due to Cervical Ribs, Dr. Archibald Donald on Malignant Disease of the Body of the Uterus, and Dr. F. Craven Moore on the Chemical, Physical, and Biological Relations of Cholesterine.

The Edinburgh Medical Journal.—The March number opens with some remarks on Empyema, based on 100 consecutive cases, by Dr. Albert E. Morison. He advises operating under local anæsthesia in adults and deprecates unnecessary removal of rib. Dr. Lewis C. Bruce continues his contribution on Acute Mania which he believes to be a toxæmia invariably due to bacterial infection. A case of Tumour of the Cauda Equina in which recovery followed operative removal of the growth is recorded by Mr. R. C. Elsworth.

The Dublin Journal of Medical Science.—In the February number is published a short paper by Sir William Smyly on the Future Teaching of Practical Midwifery. He points out the reasons for the course recently adopted by the General Medical Council and draws attention to the much greater facilities for the study of practical midwifery existing in Ireland than in England. He suggests the practical examination of a certain number of students, selected by ballot on each occasion, concerning patients suffering from gynæcological troubles as a mode of stimulating the interest of students in this branch of medical science. An abstract of a thesis by Dr. H. B. Leech on Acetonæmia does not add much to our knowledge of this condition; a similar abstract of a thesis on the Treatment of Epilepsy, by Mr. E. T. Jameson, records some unsatisfactory experiences with organic extracts and concludes with the opinion that the bromides must remain the sheet-anchor of treatment. Dr. C. G. Cumston of Boston narrates a case of Pulmonary Embolism and comments on the pathology of this affection.

The Scottish Medical and Surgical Journal.—In the March issue of this magazine is published an interesting lecture by Captain W. F. Harvey, I.M.S., and Captain Anderson G. McKendrick, I.M.S., on Immunity, in which, among other things, there is pointed out the difficulty of explaining the ingestion of bacteria in opsonic investigations on the ground merely of the activity of the leucocytes, sluggish bodies which are yet found to swallow a large number of organisms in a few minutes. The possibility of an attraction of the germs to the cells is suggested. Dr. F. Gardiner continues his account of his experiences with x rays and high-frequency treatment, the diseases treated ranging from warts and dyspepsia to locomotor ataxy and cancer. Dr. T. C. Mackenzie writes on the recognition and early treatment of Incipient Insanity and supports the idea of admitting these cases to the general hospitals.

St. Thomas's Hospital Gazette.—The February issue is chiefly occupied with a very entertaining paper on Dreams, Normal and Morbid, by Dr. G. H. Savage. The author is clearly an exceptionally favoured individual in the matter of his dream-consciousness and he tells many of his experiences in amusing style. Needless to say, he is no believer in prophetic dreams, though he admits the possibility, even the frequency, of dreams which point out where a missing article is situated, these being due to revival of an unconscious impression formed at the moment of its loss.

St. George's Hospital Gazette.—Serious medical matter is represented in the February number of this magazine only by a portion of an unsigned paper on Ancient Medicine, the text of the discourse being the work of Bartholomeus Anglicus "De Proprietatibus Rerum." Many anecdotes are quoted showing the ignorance and credulity of the time, and an account then is given of the ravages of leprosy and of the strange remedies sometimes employed for the relief of these sufferers.

Guy's Hospital Gazette.—In the issue of Feb. 22nd appears the final portion of Dr. H. C. C. Mann's paper on Arterial Blood-pressure in Health and Disease. We here get the conclusions to be derived from the whole number of observations, on which the author is much to be congratulated. Some Notes from a Clinical Lecture, by Mr. F. J. Steward, deal with the surgical aspects of tonsillitis, the opening of tonsillar abscesses and tonsillectomy, and a discussion at the Pupils' Physical Society on Constipation contains interesting matter.

London Hospital Gazette.—The number for February opens with a short but suggestive paper on Private Practice which may be commended to those recently qualified. Clearly there are more things in heaven and earth than are dreamt of by candidates for the final examination. A short note, by Mr. Frank M. Farmer, deals with the extraction of individual teeth, and Mr. Hugh Lett records a case of precocious development in a boy, aged four years, and mentions the theory that connects such a condition with affections of the suprarenal bodies. The clinical supplement is devoted to an abstract of some remarks by Dr. C. H. Miller on aortic disease. In lighter vein is an amusing account of a Chinese dinner and theatrical entertainment given in a letter from a naval surgeon.

FALMOUTH INFIRMARY.—At the annual meeting of the subscribers to the Falmouth Infirmary held on Feb. 24th it was decided that all members of the medical profession practising in Falmouth should after two years' residence be eligible for appointment as members of the honorary medical staff.

figures would support this view. Thus, coincident with the decrease in prosecutions for drunkenness, several other offences against the Licensing Acts showed a falling off which is far too large to be attributed solely to progress in temperance and in respect for law. Offences against the closing regulations, for instance, fell to half the number recorded in 1905, and the offences in connexion with the sale of drink to children and to habitual drunkards were also far fewer in number. These changes suggest that the zeal displayed by the police during the period immediately following the liquor legislation of 1901 and 1902 has abated, and it is probable that the apparent decrease in drunkenness is similarly to be regarded, at least in part, as merely an expression of a more tolerant attitude towards the convivial offender. This would at the same time account for the diminution in the number of assaults in 1906, since this diminution was almost entirely in the category of assaults on constables which, of course, in a large proportion of cases are incidental to the arrest of drunken persons.

The decided increase in crimes of lust in 1906 is interesting as showing an exaggeration of the upward tendency observable for several years past in this variety of delinquency. This tendency was manifest in nearly all the subclasses of sexual crime and was even more pronounced in homosexual offences than in assaults on women. The special frequency of sexual crimes in 1906 is referred by the editor of the statistics to the meteorological conditions of the year. The summer was unusually fine, the mean temperature of the year and of the summer months was above the average, and the number of hours of sunshine was about one-fourth more than the normal. As a large number of the offences of this class are perpetrated in the open air these conditions would obviously have increased the opportunities for their commission. A curious feature of the returns, and one the explanation of which is not very clear, is that rape and indecent assault were very much more frequent in August than in either July or September. As a general rule, these offences are pretty equally distributed over the three months mentioned and when there is any decided predominance it is usually shown in July. This is also the case ordinarily with other impulsive crimes, such as homicidal offences and attempts to commit suicide, and in the year under review these two classes of crime followed the usual course and reached their maximum in July. The exceptional prevalence of sexual crimes in August is the more singular as that month in 1906 contained fewer Sundays than July or September, and must therefore have been less influenced by week-end carousing.

Non-indictable offences, both those of a criminal and those of a merely quasi-criminal character, decreased during 1906, the total number for the year being 700,973, as against 729,727 in 1905. The decrease was spread over a great number of headings but was most marked in drunkenness, assaults, prostitution, and vagrancy offences. It is perhaps significant, in connexion with the increase in sexual crime, that the non-indictable offence of indecent exposure showed an increase of 5 per cent. on the figure for 1905.

From the tables relative to coroners' inquests it appears that the total number of such inquiries held during the year was 36,570 (or 69 per 1000 deaths), which is not far from the average for the last five years. Out of the total number of deaths which were the subject of inquest 14,293 were found to be due to natural causes or old age, 14,805 were accidental, 223 were still-births, and in 2132 cases open verdicts were returned. Excluding three cases of justifiable homicide and eight judicial executions there remain only 5105 deaths ascribed to criminal violence or culpable neglect. Of these, 3131 were cases of suicide, this number being 2 per cent. lower than the figure for 1905. This slight decrease can hardly be taken as evidence of any real check to the upward movement of suicide which has been a striking fact in English vital statistics for a good many years past. It may be noted that attempts to commit suicide did not show any similar decrease, the number reported to the police during the year amounting to 2497—the highest figure yet recorded. Of the other cases of violent death 155 were attributed to wilful murder and 110 to manslaughter. 21 persons against whom verdicts of wilful murder were returned committed suicide at the time of the murder. The number of criminal lunatics received into asylums during the year was 241, of whom 76 were found insane by verdict of jury, three were certified insane before trial, and 162 were certified insane after conviction. The total number of criminal lunatics under detention at the end of the year was 955, of whom no less than 425 had committed murder.

The comparative tables of crimes and offences since 1857 are supplemented by an interesting series of diagrams illustrating the movement in the different varieties of crime in the last 50 years. During that period the total number of indictable offences (i.e., mainly crimes of acquisitiveness) has oscillated between the extremes of 48,453 (in 1860) and 63,268 (in 1882). The absolute number of such offences in 1906 was very nearly the same as in 1857 which, in view of the growth of population in the interval, is equivalent to saying that theft has decreased by about 40 per cent. During the same period there has been a slight absolute and therefore a very considerable relative decrease in homicidal crime, while sexual offences on the contrary have tended to increase. It is suggested by the editor that the increase in the figures for the latter class may be due largely to the creation of new offences, but against this view we may put the fact that the relatively stable group of homosexual crimes shows the same change, the number of such crimes in 1906 being no less than 66 per cent. higher than in 1857.

Nisbet's Medical Directory, 1908. In two parts. Part I., Directory of Medical Practitioners; Part II., The Local Directory. London: James Nisbet and Co., Limited. *Pp. 799. Price 7s.*

THE editor in his preface states that "Nisbet's Medical Directory" has been compiled for the purpose of supplying a handy, accurate, and inexpensive list of medical men conveniently and concisely arranged in alphabetical order. There is no doubt as to the handiness of the book, and its extreme lightness is somewhat surprising when it is considered that the book comprises nearly 800 pages. With regard to its accuracy, so far as we have tested the correctness of the entries it can be fairly stated that the directory is able to stand with success a close and critical examination. The publishing price of 7*s.* is moderate in an age of competition. The arrangement of the names in a single list in alphabetical order presents great convenience; indeed, we fear that medical men may have to complain that the new directory affords a far too convenient means for the issue of circulars and samples by numerous mercantile firms. The way in which medical men are entered and described has been dictated by the intention to economise space. After the name and address follow the telephone number and the year of qualification with the various diplomas, degrees, and distinctions set forth in a concise and approved manner; the place of education is next stated, after which comes one present or past appointment, and the record concludes with the name of one publication or literary work. It was doubtless anticipated that the return of the schedules from the members of the medical profession would not be absolutely complete and accordingly we find the editor explaining in his preface that in the case of those who have not made a return the name, address, and medical titles have been adopted from the official record of their registration under the Medical Act. A local list forms the second part of the volume and this again is arranged short periods of rest or of submaximal stimulation. 2. S. Joan Meiklejohn, M.B., Ch.B., Carnegie Scholar, On the Development of the Plexiform Nerve Mechanism of the Alimentary Canal. Dr. Meiklejohn employs staining methods and his results show that the visceral (Auerbach's) plexus is formed later than, and probably as an outgrowth from, the synaptic system, and not as an independent system, afterwards forming a secondary connexion with the central nervous system. 3. T. G. Brodie, M.D. Lond., F.R.S., and Winifred C. Cullis, the Analysis of Oxygen and Carbonic Acid contained in Small Volumes of Saline Solutions. 4. H. C. Bazett, Wadham College, Oxford, Observations on the Refractory Period of the Sartorius of the Frog. 5. E. W. S. Carmichael, M.B. Edin., F.R.C.S. Edin., and F. H. A. Marshall, D.Sc., on the Occurrence of Compensatory Hypertrophy in the Ovary. The experiments of the authors of the article show that hypertrophy of the one ovary does occur after removal of the opposite one. 6. P. C. Varrier-Jones, B.A., Effect of Strychnine on Muscular Work. 7. Edward Mellanby, B.A., Creatin and Creatinin. 8. J. Theodore Cash, On the Physiological Action of the Seeds of Garcia Nutans Omphalea Megacarpa and Omphalea Triandra from Trinidad. All these seeds possess a purgative action due to the oil which they contain. They all also produce diuresis. This number contains the Proceedings of the Physiological Society on Nov. 23rd, 1907, and on Jan. 25th, 1908.

The Medical Chronicle.—The November and December numbers (1907) are designed as a memorial to the late Professor Julius Dreschfeld. A short memoir of his life and a bibliography of his published works precede the original articles which fill the rest of the two numbers; of these we have only space to record the titles. Professor A. H. Young and Professor Arthur Robinson write on Malformations of the Human Heart, Mr. G. A. Wright on Some Less Familiar Joint Affections, Dr. Robert B. Wild on the Supervention of Epithelioma on Lupus Vulgaris, Dr. W. Milligan on Labyrinthine Suppuration, Dr. Ernest S. Reynolds on Intermittent Limp, Mr. E. H. Westmacott and Professor F. A. Southam on Hyperplasia of the Superior Maxilla, and Dr. Siegmund Moritz on Oral, Laryngeal, and Nasal Symptoms of Myxœdema. Mr. William Thorburn writes on the Symptoms due to Cervical Ribs, Dr. Archibald Donald on Malignant Disease of the Body of the Uterus, and Dr. F. Craven Moore on the Chemical, Physical, and Biological Relations of Cholesterine.

The Edinburgh Medical Journal.—The March number opens with some remarks on Empyema, based on 100 consecutive cases, by Dr. Albert E. Morison. He advises operating under local anæsthesia in adults and deprecates unnecessary removal of rib. Dr. Lewis C. Bruce continues his contribution on Acute Mania which he believes to be a toxæmia invariably due to bacterial infection. A case of Tumour of the Cauda Equina in which recovery followed operative removal of the growth is recorded by Mr. R. C. Elsworth.

The Dublin Journal of Medical Science.—In the February number is published a short paper by Sir William Smyly on the Future Teaching of Practical Midwifery. He points out the reasons for the course recently adopted by the General Medical Council and draws attention to the much greater facilities for the study of practical midwifery existing in Ireland than in England. He suggests the practical examination of a certain number of students, selected by ballot on each occasion, concerning patients suffering from gynæcological troubles as a mode of stimulating the interest of students in this branch of medical science. An abstract of a thesis by Dr. H. B. Leech on Acetonæmia does not add much to our knowledge of this condition; a similar abstract of a thesis on the Treatment of Epilepsy, by Mr. E. T. Jameson, records some unsatisfactory experiences with organic extracts and concludes with the opinion that the bromides must remain the sheet-anchor of treatment. Dr. C. G. Cumston of Boston narrates a case of Pulmonary Embolism and comments on the pathology of this affection.

The Scottish Medical and Surgical Journal.—In the March issue of this magazine is published an interesting lecture by Captain W. F. Harvey, I.M.S., and Captain Anderson G. McKendrick, I.M.S., on Immunity, in which, among other things, there is pointed out the difficulty of explaining the ingestion of bacteria in opsonic investigations on the ground merely of the activity of the leucocytes, sluggish bodies which are yet found to swallow a large number of organisms in a few minutes. The possibility of an attraction of the germs to the cells is suggested. Dr. F. Gardiner continues his account of his experiences with x rays and high-frequency treatment, the diseases treated ranging from warts and dyspepsia to locomotor ataxy and cancer. Dr. T. C. Mackenzie writes on the recognition and early treatment of Incipient Insanity and supports the idea of admitting these cases to the general hospitals.

St. Thomas's Hospital Gazette.—The February issue is chiefly occupied with a very entertaining paper on Dreams, Normal and Morbid, by Dr. G. H. Savage. The author is clearly an exceptionally favoured individual in the matter of his dream-consciousness and he tells many of his experiences in amusing style. Needless to say, he is no believer in prophetic dreams, though he admits the possibility, even the frequency, of dreams which point out where a missing article is situated, these being due to revival of an unconscious impression formed at the moment of its loss.

St. George's Hospital Gazette.—Serious medical matter is represented in the February number of this magazine only by a portion of an unsigned paper on Ancient Medicine, the text of the discourse being the work of Bartholomeus Anglicus "De Proprietatibus Rerum." Many anecdotes are quoted showing the ignorance and credulity of the time, and an account then is given of the ravages of leprosy and of the strange remedies sometimes employed for the relief of these sufferers.

Guy's Hospital Gazette.—In the issue of Feb. 22nd appears the final portion of Dr. H. C. C. Mann's paper on Arterial Blood-pressure in Health and Disease. We here get the conclusions to be derived from the whole number of observations, on which the author is much to be congratulated. Some Notes from a Clinical Lecture, by Mr. F. J. Steward, deal with the surgical aspects of tonsillitis, the opening of tonsillar abscesses and tonsillectomy, and a discussion at the Pupils' Physical Society on Constipation contains interesting matter.

London Hospital Gazette.—The number for February opens with a short but suggestive paper on Private Practice which may be commended to those recently qualified. Clearly there are more things in heaven and earth than are dreamt of by candidates for the final examination. A short note, by Mr. Frank M. Farmer, deals with the extraction of individual teeth, and Mr. Hugh Lett records a case of precocious development in a boy, aged four years, and mentions the theory that connects such a condition with affections of the suprarenal bodies. The clinical supplement is devoted to an abstract of some remarks by Dr. C. H. Miller on aortic disease. In lighter vein is an amusing account of a Chinese dinner and theatrical entertainment given in a letter from a naval surgeon.

FALMOUTH INFIRMARY.—At the annual meeting of the subscribers to the Falmouth Infirmary held on Feb. 24th it was decided that all members of the medical profession practising in Falmouth should after two years' residence be eligible for appointment as members of the honorary medical staff.

muscles the fundamental optical principles are reviewed, including the prismatic action of spherical glasses. We note that the author adheres to the nomenclature κ for the angle usually measured as the angle γ; since it is the angle κ which is always measured we hope that other writers may be induced to follow his example. Disorders of the muscle movements are discussed under paralytic squint, concomitant squint, nystagmus, and so on. There is a table of the effects of paralysis of the individual muscles, including the diplopia induced, and numerous charts showing the fields of fixation are given. A section follows on the site and causes of the defective movements, treating briefly of isolated paralysis of individual muscles and unilateral and bilateral ophthalmoplegias. The pamphlet, for it is little more, is beautifully printed and illustrated and is a pleasure to read. It can be safely recommended to the student who reads German as a simple, clear, concise, and trustworthy introduction to the subject.

The Preservation of Infant Life. A Guide for Health Visitors. Six Lectures to the Voluntary Health Visitors in the Borough of St. Pancras. By EMILIA KANTHACK. London: H. K. Lewis. 1907. Pp. 92. Price 1s.—We turned to these lectures with a double interest: firstly, because they are concerned with a movement which may become of national importance; and, secondly, because they were delivered by the sister of a distinguished and lamented member of the purely scientific ranks of our profession, the late professor of pathology at Cambridge. The book is well worthy of the name which it bears and we can heartily endorse the recommendation from the medical officer of health of St. Pancras which constitutes its preface. Miss Kanthack is a certified midwife and she wisely distinguishes the line of duty between the members of her calling and the health visitors who volunteer to look after their cases when the puerperium has run its ten days. The first chapter deals with the problem of infant mortality and its alleviation by the health visiting system, and it contains much shrewd ethical advice. The scope of the remaining lectures is well indicated by their titles: "The Hygiene of Pregnancy," "Washing and Dressing the Baby" (Miss Kanthack's pupils had the opportunity of seeing this demonstrated on a life-sized jointed doll), "Infant Nutrition," "The First Year of Life and Minor Ailments," and "The Common Diseases of Infants and their Recognition." The teaching throughout is good and not the least of the book's attraction is the bright and breezy manner of its writing. We recommend it to all who are interested in a growing and important movement in national hygiene. Many "educated" mothers might profit greatly by reading it for themselves; at any rate, their babies would if their mothers followed the advice which they found in it.

Annual Report of the Imperial Bacteriologist of India for the Year 1906–1907. Calcutta: Office of the Superintendent of Government Printing, India. 1907. Pp. 27.—This report, as has always been the case, shows an immense amount of work accomplished by Dr. A. Lingard at the Imperial Laboratory at Muktesar. His labours have consisted in the preparation of the different sera and other prophylactics which occupied the attention of himself and his subordinates throughout the year. In addition experiments were conducted with a view to test the potency of hæmorrhagic septicæmic serum and also the efficacy of atoxyl in destroying the trypanosomata of surra and dourine. Experiments with the object of determining whether Indian elephants are susceptible to the trypanosoma Evansi from an equine source were carried out and observations were continued with regard to trypanosomiasis in camels. Further, four Australian horses were immunised and hyper-immunised for the preparation of tetanus antitoxin. Apart from that investigation officers of the Civil Veterinary and of the Army Veterinary Corps attended the theoretical and practical classes, whilst 49 veterinary assistants were trained at Muktesar and Bareilly. Amongst the results obtained from the above investigations the Indian elephant was proved to be insusceptible to rinderpest; spirochætosis was met with during the year under review in hill and plain cattle affected with rinderpest (this form of disease had not previously been recognised in this country); and another interesting section gives the effect of different doses of atoxyl in equines the subject of spontaneous equine trypanosomiasis. Unfortunately for India this is the last report that will be submitted by Dr. Lingard, for this hardworking and able officer has now retired from the Civil Veterinary Department after 17 years of unremitting toil. It is at least satisfactory to note that the Government of India desires to place on record its appreciation of the valuable services rendered by him to veterinary science during the period in which he has held the office of Imperial bacteriologist.

JOURNALS AND MAGAZINES.

Proceedings of the Royal Society of Medicine. Vol. I. No. 4.—Perhaps the most important communication in the present number is the paper on the Pathology and Treatment of Chronic Constipation read before the Medical Section by Dr. A. F. Hertz. His ingenious applications of the "bismuth meal" and the radiographic record of its progress through the alimentary tract are worthy of most careful study in connexion with constipation. Amongst the cases recorded in the Clinical Section those of Multiple Telangiectases and Angiomata, by Dr. Sidney P. Phillips and Dr. F. Parkes Weber, are striking. In the Electro-therapeutic Section a remarkable case of Gonorrhœal Warts which was successfully treated by x rays is figured and described by Mr. A. D. Reid. The Epidemiological Section is devoted to an important discussion on Rubella, founded on papers by Dr. E. W. Goodall and Mr. H. E. Corbin, which will take a useful place in the literature of German measles. The old question as to the existence or not of a "fourth disease" arose again in the course of the debate. Mr. W. H. Battle and Mr. S. G. Shattock contribute an elaborate and interesting paper to the Pathological Section on a remarkable case of Diffuse Cancellous Osteomata of the Femur following a Fracture, in which similar growths afterwards developed in connexion with other bones. A noteworthy feature of this paper is that it is prefaced by a neat little summary of its contents in Latin for the benefit, we suppose, of "foreign colleagues." Many will rejoice that its authors were faithful to the old *lingua franca* of science and were not tempted to fulfil their purpose in Esperanto. The Laryngological and Dermatological Sections are largely devoted to accounts of cases many of which have appeared in these columns, and the Obstetrical and Gynæcological Section is occupied with a case in which enucleation of a uterine fibroma was undertaken by Dr. Herbert Williamson in the seventh month of pregnancy. In the Therapeutical and Pharmacological Section Dr. W. E. Dixon writes on Arterio-sclerosis and Dr. A. R. Cushny on Nutmeg Poisoning.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S., with numerous coadjutors. Vol. XXXVI., No. 6. London: C. F. Clay. Feb. 28th, 1908. Price 8s.—The contents of this number are: 1. C. T. Symonds, B.A. Oxon., Wave-like Variations in Muscular Fatigue Curves. Mr. Symonds shows that when certain frog's as well as other muscles, both amphibian and mammalian, are fatigued under constant conditions with maximal break induction shocks, temporary wave-like variations can be produced in the summit line during the later stages of fatigue by any alteration in (*a*) load, (*b*) rate of stimulation, and (*c*) temperature; and also by introducing

Pure Chemistry and Medicine.

IT is hardly possible to foreshadow what bearing recent chemical discoveries may have upon medical progress but it is obvious that as our views in regard to the constitution of matter widen so is it probable that some advantage will be given to medical science. As our knowledge of chemical constitution advances so will the application of that knowledge be less empirical. It is interesting to reflect that the study of medicine in early history served as a foundation to the study of the chemical elements and of chemical interactions, and it is hardly an exaggeration to say that the present important position of chemical science is due in no small measure to the labours and researches of medical men. Even now it is not difficult to find instances of medicine indirectly stimulating the work of chemical investigation and some of the notable advances of the present time are the outcome of work pursued in the laboratories of our medical schools. Apart from this, the study of medicine necessarily involves a certain amount of chemical research. Medicine indicates to the research student useful fields for exploration, points out to him missing links in the chain of knowledge, and asks him for an explanation of the chemical changes concerned in the processes of the human laboratory which are inseparable from function.

The relationship existing between physiological chemistry and medicine is clear enough but it is not so easy to anticipate whether there is any importance likely to be connected with such discoveries as, say, the solidification of helion, the apparent transmutation of metals, and so forth. The discovery of radium was at all events a chemical triumph which has already found medical application. Looking backwards we remember how interesting a discovery was that of Priestley and Scheele when they prepared independently of each other oxygen for the first time—a purely chemical discovery which ultimately, however, gave us an insight into the nature of the respiratory process and of tissue change. Davy, similarly, when he isolated potassium and sodium in the metallic state probably regarded his discovery as of chemical importance only but we now know how this classic experiment has become of medical importance. There are indications that the elements after all are but products in different shapes, so to speak, of the same original material. Certain elements at any rate evince some properties in common, as is seen in the law of periodicity so ingeniously elaborated by Mendeléef. Amongst definite compounds there are instances of substances showing the same composition, containing, that is, the same number and kind of elements, yet which are very different in regard to their chemical and physiological behaviour. At one moment, it may be, the compound appears as a poisonous substance, at another as a quite innocuous one, and yet the composition of both is the same. If elements should after all prove to be a group of sub-entities or electrons, what wonder that indications have been obtained of a given element disappearing only to reappear as another element exhibiting totally different properties. Ramsay at all events appears to have obtained evidence that under the powerful influence of the radium emanation copper has in part degenerated into lithium, or its components have been so rearranged that the new substance is lithium. The shape which a so-called element takes would therefore seem to depend upon the stability of that element, as to whether it can be made to resolve itself into one lower in the atomic scale under the influence of the powerful agencies known to us.

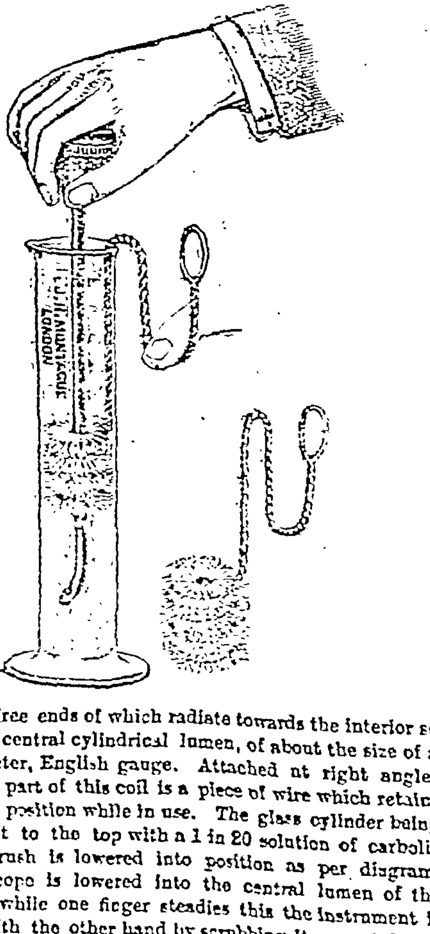
The triumph of the chemist appears in short to be only a matter of experimental facilities and here we may opportunely refer to an important announcement which was made last week in regard to the solidification of helion Not very many years ago it was thought that the solidification of hydrogen was beyond the capabilities of physical apparatus and of human power. By a species, however, of what may be called fractional processes—that is to say, by taking consecutively gases of gradually diminishing freezing points—a temperature was at last reached which forced even hydrogen to assume the solid state and at length solid hydrogen was obtained as an ice-like mass at a temperature of 257° below the zero of the Centigrade scale. A few degrees lower, namely, 14, is the absolute zero −273°. The critical temperature of helion lay within one degree of this point and as no change of state could be expected above the critical point, the solidification of this element was looked upon as improbable, if not impossible. Nevertheless, the announcement has been made that helion has been solidified and, more than that, it appears to have passed directly from the gaseous to the solid state without any indication of going through the intermediate state of a liquid. The discovery is attributed to Professor K. Ohnes of Leyden and was announced, it is stated, at a recent meeting of the Academy of Sciences of the Hague. Further particulars will be awaited with interest, especially in regard to the methods employed by which the excessively low temperatures were obtained which forced the helion to solidify. As we have indicated, this temperature must have been very close to the absolute zero, an attainment alone which is of the utmost scientific interest. It is not probable that this brilliant achievement will have any direct practical value any more than the similar discovery in regard to hydrogen has had, but the theoretical importance of it is immense. The research may throw light upon the question as to whether the element is metallic or non-metallic. If the former proves to be the case then we should have in future to write helium, if the latter then we should adhere to the termination "on." As so far there has been no convincing evidence of its metallic nature we have hitherto adopted helion as the correct name.

Even remote as these low temperature experiments would appear to be from any medical application, yet we cannot forget their importance in regard to one great question—that of vitality. Professor Dewar's brilliant achievements in this field of work have brought out one remarkable fact in biological science, and that is the extraordinary resistance even to excessive cold of a vital combination. Thus, although chemical action tends to cease at

New Inventions.

A CYSTOSCOPE BRUSH.

I designed this brush while house surgeon at St. Peter's Hospital recently to meet a real want and it was successfully employed in all the cystoscopic work there. Hitherto during the progress of endoscopy the cystoscopes were for purposes of efficient sterilisation always kept standing in a glass cylinder filled with acidum carbolicum liquefactum. In cold weather it is impossible to prevent the solidification of the carbolic acid unless heat is employed. The cystoscopes were constantly going out of working order and eventually it was proved to be due to this acid. Not only was the too powerful acid impairing the joint between the lamp and the other portion of the cystoscope, but the heat of the fluid was causing the mirror inside the instrument to "run," and thus become useless for purposes of reflection. With this new device a 1 in 20 solution of the carbolic acid suffices. The brush consists of a double strand of wire arranged in a coil. Entwined in this wire are hair bristles of equal length, the free ends of which radiate towards the interior so as to form a central cylindrical lumen, of about the size of a No. 10 catheter, English gauge. Attached at right angles to the upper part of this coil is a piece of wire which retains the brush in position while in use. The glass cylinder being filled almost to the top with a 1 in 20 solution of carbolic acid, the brush is lowered into position as per diagram. The cystoscope is lowered into the central lumen of the brush, and while one finger steadies this the instrument is sterilised with the other hand by scrubbing it up and down. The brush should not be kept in the carbolic solution perpetually, otherwise the bristles become temporarily soft; it should be hung up when not in use.



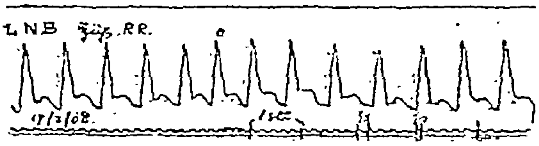
It was made for me by Mr. J. H. Montague, of 69, New Bond-street, London, W.

R. J. Willan, M.B., B.S. Durh., M.R.C.S. Eng., L.R.C.P. Lond.,

Late house surgeon to St. Peter's Hospital for Stone and Urinary Diseases, London; late house surgeon to Royal Infirmary, Newcastle-upon-Tyne.

TIMEMARKER ATTACHMENT FOR DUDGEON'S SPHYGMOGRAPH.

The apparatus consists of a clockwork box measuring 1⅛ inches × 1 inch × ⅝ inch, to which is attached a lever with writing style that records the time on the smoked paper in tenths of a second. The clockwork being quite separate from that driving the smoked paper any alteration in the rate of travel of the paper is correctly recorded. Since the paper rarely travels steadily and is very liable to catch momentarily, while the driving mechanism is not proportionately checked, any timemarker driven by the same machinery that drives the paper is untrustworthy. The whole apparatus is simply and quickly attached by withdrawing the two top corner screws of the sphygmograph and then using them to screw the timemarker on to the top of the machine. Thus no alteration at all is needed and it can be fitted immediately to any "Dudgeon." When ordering, the breadth of the smoked paper should be mentioned. The timemarker is sold in a box which will carry the sphygmograph with the timemarker attached. The great advantage of this apparatus is that it gives a rectangular tracing, each complete movement being one-fifth of a second, but each half movement, as represented by each horizontal line, gives one-tenth of a second.



Messrs. G. Horstmann and Sons, 13, Union-street, Bath, made these timemarkers for me and the price is about 35*s.* I inclose a specimen of a tracing.

L. N. Hesketh Biggs, M.D. Edin.

Frampton-on-Severn, Glos.

Looking Back.

FROM

THE LANCET, *SATURDAY*, March 13th, 1830.

MEDICAL ARRANGEMENTS FOR THE NEW POLICE.

To the Editor of The Lancet.

Sir,—Perhaps you are not aware that the Commissioners of Police, (of course with the sanction of Mr. Peel) have determined to send their sick men to the dispensaries and hospitals, for medical assistance, instead of appointing district-surgeons, as was at first contemplated.

This information was communicated to me by a surgeon of great respectability, who had an interview with one of the commissioners a short time since.

Can anything so flagrant and unjust be permitted to pass, without the censure which it merits? Can the sacred name of charity be thus perverted? What will the dispensary system next bring upon the profession?

I suppose Mr. Peel will, ere long, for two guineas per annum, supply his family and servants with medical attendance and medicines, as I believe the physicians and surgeons from these establishments attend patients at their own houses.

Without your continued and powerful exertions to repress these growing evils, and a determination on the part of the general practitioners, to unite and assist you in *your* laudable endeavours, I predict that this industrious and meritorious class of men, will soon be deprived of more of the emoluments which they have hitherto received, and to which they are justly entitled.

I am, Sir, your well-wisher,

London, Feb. 20th, 1830. A Surgical Reformer.

Idiosyncrasies.

WE are assured by the Declaration of Independence that all men are born equal, yet even if it be so in matters political it is certainly not true of their physical natures. We are so accustomed to generalisation in physiology and medicine that we are prone to lose sight of the fact that the individual deviations from that which we are disposed to call the normal are many and great. In disease it is not sufficiently recognised that predisposition is often of equal importance with the exciting cause and sometimes it is of even greater importance. In his recent address in Paris delivered before the Faculty of Medicine Sir DYCE DUCKWORTH emphasised the fact that many of our great predecessors in medicine appreciated more exactly than most of us do at the present time the immense importance of the personal factor in disease. They may have carried the idea to excess but it was based on truth and every practical clinician knows that there must be predisposing factors in the body to lead to the production of a disease. The germ may be present but it cannot grow if the soil is not fitted for it. Against some human bodies germs seem to make assaults in vain, though they may attack with ease the bodies of others. Within the last few years we have learned a little of the conditions underlying this immunity. We know that there exist in the fluids and solids of the body substances which can destroy or neutralise the toxins of the attacking microbes, and the more we investigate the matter the more our astonishment increases at the complexity of the methods by which the body endeavours to shield itself against the assaults of its microbic foes. Even more surprising, however, are the differences existing between two individuals in their means of defence, and the vulnerability of some is especially noteworthy. These differences, however, can be to some extent explained by the possibility that so complex a mode of defence may readily fail owing to an inadequacy in some small part. When, however, we turn from diseases produced by micro-organisms to the morbid states arising from drugs we meet with conditions even more surprising. Though as a rule drugs are fairly uniform in their action, yet exceptional symptoms are by no means rare. The iodides and bromides can be taken by most people in fairly large doses but in a few severe symptoms may develop even after minute quantities. Opium has been known to give rise to convulsions and many other instances could be mentioned where drugs have caused unusual symptoms when given in ordinary doses or where they have caused severe symptoms when administered in minute quantities.

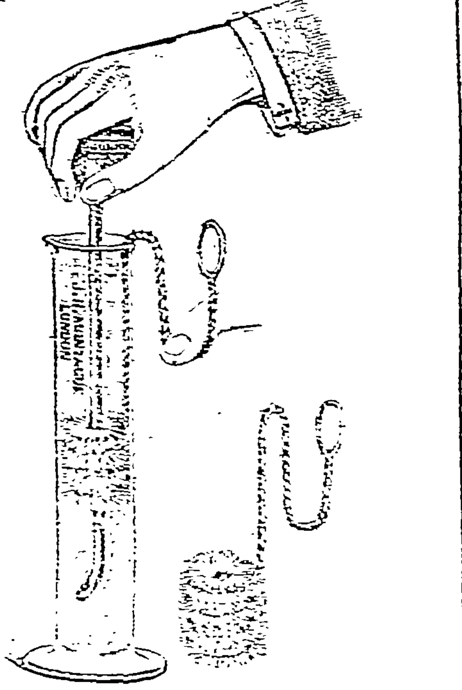
Closely allied to these anomalous effects of drugs are the results sometimes caused by articles of food. There is hardly any food which at some time or other has not produced strange symptoms, and this quite apart from any decomposition in the food itself. The patient is peculiarly susceptible to that particular article of diet and is affected by it whenever he partakes of it, though others may on the same occasions eat it with impunity. From some unknown change in the constitution of the patient's body the should-be harmless food acts as a violent poison and in some cases life itself may be threatened. Eggs are pre-eminently responsible for such toxic manifestations and in THE LANCET of March 7th (p. 716) appeared an account by Dr. A. T. SCHOFIELD of a boy 13 years old who could not eat eggs in any form. If he partook of an egg the saliva would flow, the lips burned, there was nausea, an urticarial rash broke out, the face became puffy, and some dyspnœa arose. On one occasion he suffered after eating a bun which had been glazed with white of egg. The effect was probably not produced through the nervous system, as a raw egg applied to the surface of the skin gave rise to a blister. In cases like this the result is not due to dislike or to "suggestion," for the harmful effect is produced even when the patient is unconscious that any egg is present in the food. Dr. SCHOFIELD suggested that the egg albumin acted in some way on the serum albumin so as to cause transudation, but Dr. R. HINGSTON FOX in a letter in the present issue of THE LANCET offers the theory that eggs contain a powerful decalcifying substance which precipitates the calcium salts in the blood and thus diminishes the coagulability and leads to the transudation of lymph. Cases of egg poisoning are not rare. Rice is another food which is liable to give rise to toxic symptoms and the attacks are generally asthmatic in nature. In one susceptible case some soup had been thickened with ground rice and it gave rise to a severe attack of dyspnœa. In another instance the difficulty of breathing arose after the patient had had some bottled beer to which some grains of rice had been added in order to excite fresh fermentation. A case has been recorded in which honey always produced swelling of the tongue, frothing of the mouth, and blueness of the fingers, and these signs were especially well marked if the honey had been eaten in the comb. It has long been known that if the bees feed on certain flowers the honey which they make may cause various symptoms. It will be remembered that XENOPHON describes in the "Anabasis" headache as being caused by the eating of the honey of a district through which the Ten Thousand passed. It is certain that different honeys differ greatly in their flavouring constituents and "heather" honey, produced by bees which feed on the moors, is readily recognisable. A case has been described in which the eating of figs produced itching of the palate and fauces. Dr. G. F. STILL in a recent lecture at the Hospital for Sick Children related a case of a boy aged about 14 years who could not take porridge as it made his face swell. As Dr. STILL felt a little sceptical the boy was given some porridge in Dr. STILL'S presence and before the boy had finished his meal the face began to swell and within 20 minutes it was so swollen that he could not see out of one eye. Strawberries also are liable to give rise to troublesome symptoms in susceptible subjects.

In all these cases the regular repetition of the symptoms whenever the supposed cause is taken excludes the possibility of the effect being due to some decomposition or impurity. One of the most remarkable facts connected with this curious subject is that the result may be caused by quantities extremely small. As to the truth of these poisonings there can be no doubt and in time we may discover the mode of action. Curiously very little has been done to attempt to remedy these troublesome idiosyncrasies, and they may prove very troublesome; for instance, if a child can never take egg in any form his dietary is distinctly limited, as egg enters a good deal directly

New Inventions.

A CYSTOSCOPE BRUSH.

I DESIGNED this brush while house surgeon at St. Peter's Hospital recently to meet a real want and it was successfully employed in all the cystoscopic work there. Hitherto during the progress of endoscopy the cystoscopes were for purposes of efficient sterilisation always kept standing in a glass cylinder filled with acidum carbolicum liquefactum. In cold weather it is impossible to prevent the solidification of the carbolic acid unless heat is employed. The cystoscopes were constantly going out of working order and eventually it was proved to be due to this acid. Not only was the too powerful acid impairing the joint between the lamp and the other portion of the cystoscope, but the heat of the acid was causing the mirror inside the instrument to "run," and thus become useless for purposes of reflection. With this new device a 1 in 20 solution of the carbolic acid suffices. The brush consists of a double strand of wire arranged in a coil. Entwined in this wire are hair bristles of equal length, the free ends of which radiate towards the interior so as to form a central cylindrical lumen, of about the size of a No. 10 catheter, English gauge. Attached at right angles to the upper part of this coil is a piece of wire which retains the brush in position while in use. The glass cylinder being filled almost to the top with a 1 in 20 solution of carbolic acid, the brush is lowered into position as per diagram. The cystoscope is lowered into the central lumen of the brush, and while one finger steadies this the instrument is sterilised with the other hand by scrubbing it up and down. The brush should not be kept in the carbolic solution perpetually, otherwise the bristles become temporarily soft; it should be hung up when not in use.



It was made for me by Mr. J. H. Montague, of 69, New Bond-street, London, W.

R. J. WILLAN, M.B., B.S. Durh., M.R.C.S. Eng.,

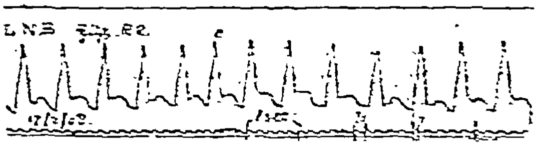
TIMEMARKER ATTACHMENT FOR DUDGEON'S SPHYGMOGRAPH.

THE apparatus consists of a clockwork box measuring 1¼ inches × 1 inch × ⅝ inch, to which is attached a lever with writing style that records the time on the smoked paper in tenths of a second. The clockwork being quite separate from that driving the smoked paper any alteration in the rate of travel of the paper is correctly recorded. Since the paper rarely travels steadily and is very liable to catch momentarily, while the driving mechanism is not proportionately checked, any timemarker driven by the same machinery that drives the paper is untrustworthy. The whole apparatus is simply and quickly attached by withdrawing the two top corner screws of the sphygmograph and then using them to screw the timemarker on to the top of the machine. Thus no alteration at all is needed and it can be fitted immediately to any "Dudgeon." When ordering, the breadth of the smoked paper should be mentioned. The timemarker is sold in a box which will carry the sphygmograph with the timemarker attached. The great advantage of this apparatus is that it gives a rectangular tracing, each complete movement being one-fifth of a second, but each half movement, as represented by each horizontal line, gives one-tenth of a second.



Messrs. G. Horstmann and Sons, 13, Union-street, Bath, made these timemarkers for me and the price is about 35s. I inclose a specimen of a tracing.

Looking Back.

FROM

THE LANCET, *SATURDAY*, March 13th, 1830.

MEDICAL ARRANGEMENTS FOR THE NEW POLICE.

To the Editor of THE LANCET.

SIR,—Perhaps you are not aware that the Commissioners of Police, (of course with the sanction of Mr. Peel) have determined to send their sick men to the dispensaries and hospitals, for medical assistance, instead of appointing district surgeons, as was at first contemplated.

This information was communicated to me by a surgeon of great respectability, who had an interview with one of the commissioners a short time since.

Can anything so flagrant and unjust be permitted to pass, without the censure which it merits? Can the sacred name of charity be thus perverted? What will the dispensary system next bring upon the profession?

I suppose Mr. Peel will, ere long, for two guineas per annum, supply his family and servants with medical attendance and medicines, as I believe the physicians and surgeons from these establishments attend patients at their own houses.

Without your continued and powerful exertions to repress these growing evils, and a determination on the part of the general practitioners, to unite and assist you in your laudable endeavours, I predict that this industrious and meritorious class of men, will soon be deprived of more of the emoluments which they have hitherto received, and to which they are justly entitled.

I am, Sir, your well-wisher,
London, Feb. [illegible], 1830. A SURGICAL REFORMER.

have some latent focus of tuberculosis in them (as has been asserted) it would not follow that the people who die on whom no necropsy is performed are affected in the same ratio. We can appreciate the urgency that exists for the prevention of tuberculosis and for the securing of a good milk-supply to our communities without the addition of such picturesque arguments; we are sure that Mr. Douglas accepted this one on trust with the best of faith, and as it is not the first time that we have heard it, it seems well to raise a protest.

THE HEALTH OF MR. CHAMBERLAIN.

WE gather from a correspondent at Cannes that Mr. Chamberlain's condition is one of steady improvement and progress towards recovery. He soon got over the slight fatigue of his journey from England and is in good general health and spirits, while he is leading less and less an invalid life. He enjoys walking in the garden of his beautifully situated villa, commanding fine views of the neighbouring coast and mountains, sees his friends daily, and takes a keen interest in public affairs.

THE VARIETIES OF TUBERCULIN.

THE number of preparations made from tubercle bacilli and administered under the name of tuberculin, with or without certain descriptive letters, has increased to such an extent that considerable confusion exists in the literature of the subject. It is of the utmost importance that the practitioner should know which form he is giving and the general nature of the particular processes by which it has been obtained. The preparations which are best known in this country are, first, Koch's old tuberculin which is sometimes referred to as tuberculinum Kochi; secondly, Koch's new tuberculin, or tuberculin T.R.; thirdly, Bacillen-emulsion or emulsion of bacilli; fourthly, pulverised tubercle bacilli; and, lastly, the recently introduced Calmette's tuberculin-ophthalmic reagent. The old tuberculin is prepared from four- to six-weeks old glycerine broth cultures of tubercle bacilli boiled for an hour, evaporated down to one-tenth, and then filtered so as to remove the bacilli themselves. The new tuberculin, tuberculin T.R., is prepared by drying living virulent cultures *in vacuo*, grinding them up into a very fine dust, and after extracting certain soluble constituents with saline solution the residue is rubbed up with water to form an emulsion. "Bacillen-emulsion" is prepared from pulverised bacilli, without previous extraction with water, equal parts of glycerine being added, so that one cubic centimetre contains five milligrammes of bacillary substance. Pulverised tubercle bacilli are used for making emulsions for opsonic and other tests. Calmette's reagent is a solution in sterilised water of the precipitate obtained from old tuberculin by alcohol, so as to obtain a solution free from glycerine. Other preparations which have been tried comprise Klebs's tuberculocidin and antiphthisin, Hirschfelder's oxy-tuberculin, Hahn's tuberculoplasmin, Beraneck's tuberculin, Landmann's tuberculol, Maragliano's water extract, and Denys's tuberculin B.F. (bouillon filtré), while Spengler writes favourably of a filtered bouillon from bovine bacilli described as P.T.O. (Perlsucht-tuberculin-original). We have received a copy of a small pamphlet published by Messrs. Meister, Lucius, and Brüning, of Hoechst o.M. and London, entitled "New Tubercle Bacilli Preparations," in which some valuable information is given in regard to the nature and use of many of the more important preparations, including some of comparatively recent introduction. Among these may be mentioned T.O.A. (tuberculin-original-alt), which appears to correspond to Denys's bouillon filtré; P.T.O., a similar preparation from bovine bacilli to which reference has already been made; vacuum tuberculin and bovine vacuum tuberculin, which differ from the old tuberculin in the avoidance of high temperatures in their preparation. All of these substances are prepared by filtration and are thus free from bacilli. A form of tuberculin adapted for the Calmette ophthalmo-reaction is also described under the name of "Tuberculosis-diagnostic Hoechst." This is 0·1 per cent. solution of a glycerine-free desiccated tuberculin and is thus only one-tenth of the strength of that originally employed by Calmette. Tuberculin T.R., Bacillen-emulsion, new bovine tuberculin (tuberculin P.T.R.), and bovine tubercle bacilli emulsion are also referred to, while the preparations of dilutions and the dosage and methods of administration are described. It may here be said that the doses recommended are in most cases larger than are usually recommended in this country, especially since the work of Wright and Bulloch upon the administration of tuberculin controlled by determination of the opsonic index. The pamphlet is likely to be useful in indicating the nature of some of the forms of tuberculin at present on the market, though in this respect it would be improved by further details in regard to the preparation of some of them, and by an indication that smaller doses, calculated to produce an effect upon the protective mechanisms of the body without producing disturbance of the body temperature, are recommended by some authorities. It cannot be too strongly urged that in using tuberculin of any form, either as a diagnostic or as a therapeutic measure, the practitioner should be quite clear in his mind as to the exact action of the preparation which he decides to employ and as to the indications for its administration. Tuberculin is in many forms very potent and is obviously not to be administered indiscriminately to cases of tuberculous disease, at any rate until our knowledge of its effects is much greater than at present.

THE FUMES OF THE MATCH.

THE evolution of the lucifer match is interesting. The present match is scarcely yet 100 years old, for in 1820 the tinder-box was the exclusive means of initiating a light, a comparatively modern survival of the archaic flint and steel. To this day the tinder-box may be found in some houses but it is kept more as a relic than as a practical appliance. Whatever may be said of the inconveniences or offensiveness of the old tinder-boxes, the modern match can hardly claim to be above criticism in regard to hygienic considerations, although its extreme convenience must be admitted. Indeed, the lucifer match has become an absolute *sine quâ non* of existence. It is a pity, however, that, like the modern explosives used in firearms, it cannot be made smokeless, or better still to give off products of combustion which hygienically speaking may be disregarded. Everyone knows how pungent and offensive are the fumes of the modern match and when the composition of modern matches in general is considered this is not surprising. Amongst the ingredients used, either on the match itself or on the rubber on the box, are phosphorus, sulphur, sulphide of antimony, red lead, sulphide of mercury, and lead chromate. The ignition and combustion of the match therefore result, according to the combustible materials entering into its composition, in the copious evolution of sulphurous and phosphoric acids or fumes containing lead, antimony, or mercury, all of which are decidedly poisonous. The amounts in each individual match-head may be small but there are occasions when the number of matches so used is great or when the space in which they are ignited is limited. It would not be surprising to find, for example, that in the atmosphere of the smoking-room or of the smoking concert hall or of the railway carriage the presence of excessively low temperatures the vitality of seeds is unaffected when they are exposed to a temperature *not far off absolute zero.* Lastly, as showing how the discoveries of more or less pure chemistry may after all possess some significance for medicine should be mentioned the application of low temperatures for obtaining cell juices. Moulds, yeast, and bacteria have been reduced to a brittle state, have been crushed, and their respective cell juices have been obtained for examination. In this way the typhoid organism has been crushed, and within itself a toxin has been found. We are thus brought to distinguish between a toxin within the cell and a toxin which is extra-cellular. Truly the question of what practical use is this or that discovery to us, often betrays a scornful impatience unworthy of scientific men.

The Supply of Midwives.

WITH a view of throwing some light on this question MRS. HEYWOOD JOHNSTONE has collected statistics from all the counties of England and Wales showing the number of trained and *bonâ-fide* midwives available at present, the total number of births per annum in the corresponding county areas, and the deficiency in the number of midwives which will exist in 1910 when the full provisions of the Midwives Act will come into force. To obtain the latter figures she has calculated that 50 per cent. of the total births are attended by midwives and that one midwife is required to every 25 births; while at an estimated expenditure of £20 per midwife for training the total sum required to meet the deficiency in the number, which, exclusive of London, amounts to 4168, would be £83,360. We need not remind our readers that after the beginning of 1910 any uncertified woman is forbidden to attend for a fee her neighbour in her confinement except in an emergency. As at the present time there are large numbers of untrained women who are accustomed to render this service to their neighbours the refusal of the law to allow any such custom to continue after January, 1910, must be attended by a very serious state of things unless prompt measures are taken to increase the present scanty number of certified midwives in most of the counties of England and Wales. The difficulties to be overcome are obvious and serious—viz., the difficulty in persuading the proper class of women to take up this occupation, their inability to provide without assistance the necessary funds for their training, and, most important of all, the fact that even when properly trained and certified in only too many instances they will be quite unable to earn a living wage if they follow the occupation of midwife alone, as the provisions of the Act require. The best method of overcoming these grave difficulties has for some time occupied the minds of all those who are interested in insuring the satisfactory working of this important Act.

MRS. HEYWOOD JOHNSTONE in her pamphlet adumbrates a scheme which she thinks might serve to solve the serious problem of supplying trained women to take the place of the untrained neighbour of the present day. She realises clearly that it is impossible to supply properly trained midwives for all parts of the country who will be able to earn a living by the exercise of such an occupation alone. It is also beyond the limits of possibility to suppose that sufficient funds will be forthcoming either from the public or from the Government to enable the necessary financial assistance to be given to any large number of these women. She believes, however, if it were found possible to train a half or even a smaller proportion of the untrained women who at the present time attend their neighbours for a small fee, that in this way the gap which must inevitably exist when the Act comes fully into force in 1910 would be met. Such women would be drawn from the same class as the patients themselves, an obvious advantage, and further, their earnings would be in addition to their ordinary income and they would not be dependent entirely on them for their livelihood. It is true that such a scheme could only cover a moiety of the deficiency that would exist but the remainder could then more readily be provided for by the provision of trained midwives who would devote all their time to such work. The expenses of training the village women would have to be met by grants from the local supervising authorities and the means for their training by an increase in the number of provincial centres in which such training can be given, by an increase in the number of midwives and medical men allowed to undertake such training, and, above all, by throwing open the Poor-law infirmaries as training centres.

Under this scheme the difficulty of the maintenance of these women is by no means so great as it must be in the case of trained midwives who look to their work wholly to support them. Such trained women would in most instances in the country be content with the small addition to their income which their training would give them, while such as worked in towns could probably earn a living wage. Some would no doubt require financial help and such help might be provided for by the promoting of maternity clubs to which all women requiring the services of a midwife should be encouraged to subscribe, by the assistance of the boards of guardians in the case of the very poor, or by the assistance of local benevolent societies and nursing associations. The supervising authority as before would be the county councils, given a free hand to deal as they thought best with their own areas. As MRS. HEYWOOD JOHNSTONE truly points out, if we are to attempt to supply the whole country with highly trained midwives dependent upon their earnings for their livelihood then the task seems incapable of fulfilment, but if we aim only at giving back to the villagers their helpful neighbours with sufficient knowledge to enable the latter to carry on the work with safety to their patients, then we may well hope that the task is not an impossible one to carry to a successful conclusion. It would require the provision of a considerable sum of money and a large increase in the number of local training centres. So long, however, as the Central Midwives Board continues to withhold its "recognition" from Poor-law establishments to the extent that it does at present—for example, only six of the 31 boards of guardians in London and 13 of some 600 provincial boards are recognised for training midwives—it is difficult to see how such an increase is to be provided.

according to the statement given, 8000 righteous pledged against the use of tobacco, while 'many of them have also pledged themselves against drinking, gambling, and profane language.' Everyone must feel that it would be good both for the physical and moral well-being of the coming race if this number could be increased indefinitely. Bishop Welldon spoke at the afternoon meeting and said that no one in Manchester had fought against smoking by boys more than he had. As head-master at Harrow he had frequently punished boys for smoking, and those boys had since grown up to thank him, and many of them now filled important positions. He spoke of juvenile smoking as the cause of serious physical deterioration, and said that 'it was regrettable to find that Great Britain was the last of all the nations to deal with the subject by legislation.' In view of a statement made by Captain Rigg, the treasurer, at the evening meeting that no less than 100,000,000 cigarettes were sold weekly in this country in penny packets, and that £10,000,000 annually were spent by the young people of the country on what he called 'the odious cigarette,' the society has plenty of work before it. But if all indulgence in tobacco were cut off what prospect but that of starvation would there be for those interested in tobacco from the sowing of the seed to the final transformation of the product into smoke? This is no argument if tobacco has no good points at all, but it is difficult to disregard the testimony of its old and widespread use not only by the luxurious and idle but by some of the most strenuous workers and intrepid travellers in every region of the globe who have obtained from it comfort and solace."

PROTECTED VERMIN.

IN a recent issue of THE LANCET[1] it was stated that among ancient Germans and Scandinavians rats were "reverenced as being the souls of the dead." The belief had died out before the advent of Christianity, for the Lesser Edda, written in semi-pagan times at the beginning of the thirteenth century in Iceland, gives us no hint on the subject. It is therefore to be inferred that the rat was on its way to being regarded as vermin in our modern sense of the word at the time when this classic treatise on old Norse beliefs was compiled. In that mystical natural history book "The Hortus Sanitatis," which was originally the work of Johann von Cuba, an Augsburg physician in the fifteenth century, the rat appears as a creature still endowed with certain magical properties. We read in the Hortus that the urine of a rat in heat is capable of rotting unprotected human flesh and so causing deep wounds incapable of proper cicatrisation. Rat dung, moreover, is cited as a potent cure for baldness. Having been first sacred and then magical and medicinal, the rat may quite possibly have been allowed to increase among scanty and superstitious northern populations in the barbaric period of European history. We hear of rats travelling in hordes, as in the story of the "Pied Piper of Hamelin," and these hordes may originally have been allowed to increase on sufferance. The same thing may have happened in the case of the wolf which in some countries was perhaps not exterminated so long as it did no great harm. Edmund Spenser in a curious passage says of the Elizabethan Irish that they regard the wolf as "a gossip" or compeer, and we know that the wolf was not killed off in Ireland till perhaps the early days of the eighteenth century. The Eastern pariah dog, again, enjoys a certain immunity from persecution quite out of keeping with the bad name given to it in the Bible and in Turkey and India. To primitive minds scavengers, such as dogs and rats, often become sacred through what they eat. It has been suggested that in the days of neolithic man the dog acquired a kind of accursed sanctity through gnawing human corpses where they fell—in the door of the household cave, it may be—and thus swallowing and becoming the tenements of the souls of dead tribesmen of note. And according to the elder Mr. Kipling ("Man and Beast in India") it is still accused of man-eating propensities through haunting the burning-ghats or Hindoo cremation grounds. Substitute rat for dog, and the preservation of rats as "the souls of the dead" may be accounted for. That the superstitious regard for vermin of all kinds leads to their increase and to the spread of disease is, of course, obvious.

THE HAMPSTEAD GENERAL HOSPITAL: ELECTION OF MEDICAL STAFF.

A MEETING of the council of the hospital was held on Thursday afternoon, March 5th, when it was unanimously resolved that the recommendation of the selection committee for the appointments to posts on the in-patient staff of the hospital should be adopted. The selection committee consisted of Sir Richard Douglas Powell, President of the Royal College of Physicians of London; Mr. Henry Morris, President of the Royal College of Surgeons of England; and Mr. Edmund Owen, chairman of council of the British Medical Association, these three gentlemen having consented to assist the hospital at a time of great strain. The letter set out below shows the circumstances of their appointment as a selection committee and gives the names chosen:—

To the Chairman of the Council of the Hampstead General Hospital.

SIR,—In accordance with the request made to us by the Council of the Hampstead Hospital, and communicated to us through the Executive Committee of King Edward's Hospital Fund for London, we have selected from the lists of candidates submitted to us the names of the following physicians and surgeons, and have arranged them in the order in which we desire to recommend them. We are informed that Mr. Edmund Owen has already accepted office as one of the surgeons at the request of the Council.

Physicians.	*Surgeons.*
1. Dr. G. A. Sutherland.	1. Mr. J. Jackson Clarke.
2. Sir John Broadbent.	2. Mr. W. H. Clayton-Greene.

We remain, Sir, yours faithfully,
(Signed) R. DOUGLAS POWELL.
HENRY MORRIS.
EDMUND OWEN.

London, March 4th, 1908.

It will, we fear, be some little time before the friction arising from all the circumstances of an unfortunate situation is smoothed away, but we trust to the good sense of all concerned not to perpetuate the trouble wantonly.

DISPLACEMENT OF THE LARYNX IN ANEURYSM OF THE ARCH OF THE AORTA.

A NEW sign observed in some cases of aneurysm of the arch of the aorta is described by Dr. E. Boinet in the *Gazette Médicale de Paris* of Jan. 15th last. It consists in a displacement of the larynx downwards and to the left. It is wanting in cases of chronic aortitis and of tumours and glandular affections in the mediastinum. The depression of the larynx may be very marked; in one of Dr. Boinet's cases, the nature of which was subsequently confirmed by necropsy, the cricoid cartilage was actually situated below the level of the horizontal plane passing through the sternal notch, rendering tracheotomy impossible. As a result of this drawing down of the larynx it may also be much less movable; in one case it was practically immobile, even on deglutition and on movements of flexion and extension of the neck. But these conditions of depression and lessened mobility may occur in association with affections of the tracheo-bronchial glands and with mediastinal tumour. In aneurysm of the arch of the aorta there is in addition a deviation to the left with slight torsion, which, however, is only produced by an aneurysm of some size. The effect produced is that the left lateral aspect of the larynx is more inclined and is drawn downwards, and indirectly into the diet of a child. Dr. **SCHOFIELD**, whose case we mentioned above, has endeavoured to establish a tolerance for eggs in his patient and he has succeeded. A pill containing the ten-thousandth part of a raw egg with a little calcium lactate to assist in stopping the transudation of serum was given every day. The quantity was gradually increased and by the end of six months the daily amount given was one thirty-third part of an egg. A month later the boy was taking a sixth of an egg each day and yet no symptoms were produced. As a test he was given a pudding which he was told contained egg though none was present but no symptoms were produced. Ultimately he was able to eat an egg a day without harm. This very successful result suggests that many, perhaps most, of these cases of intolerance could be cured and some such treatment deserves a trial, for the peculiarity is often very troublesome to its unfortunate possessor.

---

[1] THE LANCET, Feb. 15th, 1908, p. 507

Annotations.

"Ne quid nimis."

THE LATE IMPERIAL BACTERIOLOGIST TO THE GOVERNMENT OF INDIA.

THE retirement of Dr. Alfred Lingard from the position which he has held for the last 17 years of Imperial bacteriologist to the Government of India merits more notice than that given to it by the scanty announcement in the *Gazette* when we consider the vast amount of good work which has been executed under his direction. Dr. Lingard went out to India in 1890 and was first stationed at Poona, where he carried out many investigations as regards rinderpest, anthrax, and trypanosomiasis (surra). In the year 1891 he suggested to the Government of India the advisability of building a large laboratory on the hills where all important diseases of animals could be investigated and means could be devised to combat them. After the lapse of two years this proposal was sanctioned and Dr. Lingard proceeded to select a site on the hills near Almora at Muktesar; after some time a suitable one was discovered. This had to be cleared of the vegetation and trees before the building operations could be commenced and the laboratory at Muktesar was finally completed, furnished, and equipped in 1898. In the year 1899 Dr. Lingard went on leave to England and whilst on his leave a great misfortune occurred, for the laboratory was totally destroyed by fire; the valuable equipment was lost, whilst in addition he sustained a grievous blow by the destruction of his large library. For the second time, therefore, in 1900, a laboratory was constructed and the buildings were completed, refurnished, and refitted in 1903. Again in 1906 and 1907 separate and isolated laboratories were erected, together with the necessary sheds and stables. Thus there are now separate buildings for the preparation of tetanus antitoxin and of mallein for glanders, and for the investigation of hæmorrhagic septicæmia and of *charbon symptomatique*. To show how the work has progressed it may be mentioned that in 1890 Dr. Lingard commenced his labours with one native Goanese assistant in Poona. In 1907, when he left, there were two veterinary surgeons acting as assistants, three European laboratory assistants, and two veterinary graduates on the staff. The large output of valuable work was effected during the hot weather at Muktesar, whilst during the cold weather the investigations were transferred to another laboratory situated at Bareilly in the plains. Thus far we have only indicated the part played by Dr. Lingard in the foundation and erection of these laboratories; these on their completion have been the seat of much notable research work and of many important investigations. To name but a few examples, thousands of doses of sera for rinderpest, anthrax, hæmorrhagic septicæmia, and *charbon symptomatique*, and of mallein and tetanus antitoxin have been prepared and distributed; whilst successful researches in the treatment of trypanosomiasis with arsenic followed by mercury, with arsenic and trypanroth, and with atoxyl have been carried out. We may also draw attention to the valuable reports in 1904, one on rinderpest and the other on dourine, the latter being followed in 1906 by a third showing the successful treatment of dourine by arsenic and trypanroth. Lastly, he discovered a successful treatment for surra. Dr. Lingard has accomplished all this work, living often for many months a solitary life on the hill-top on which his laboratory was erected. This laboratory, devised by himself, has been described by the commissioners who were sent out to Africa and the East from the Institute for Marine and Tropical Diseases, Hamburg, as "indubitably one of the finest in India and having nothing to fear with the largest and best-fitted institute in Europe." Dr. Lingard returns to Europe with the satisfactory record of hard work ungrudgingly performed—work which has been of the utmost value in preventing some of the fatal diseases affecting cattle. We trust that his name will appear in a future *Gazette* amongst the honours list.

MODERN DAIRY PRACTICE.

AN interesting paper was read by Mr. Loudon M. Douglas before the Royal Society of Arts on March 4th, in which he reviewed in an untechnical manner the dangers to be apprehended from the use of an impure milk-supply and the means adopted by well-equipped modern dairies to counteract them. He first showed his audience the darker side of the picture, however, for he admitted the conditions under which some of the byres in the United Kingdom are conducted to be thoroughly repulsive and in many cases innocent of the primary requirements of cleanliness. A reactionary class of dairymen still resents bitterly the attacks made on their profits in the cause of the public interests; but improved technical education is training the opinion of the younger generation of the milk trade in favour of cleanly and scientific methods of production, and this is the spirit which Mr. Douglas, like all advocates of scientific advance in any direction, begs the Government to take advantage of, and not to be niggardly in encouraging a useful and indeed vital branch of research. He quoted the example of other countries in securing a proper milk-supply and told of a certain byre in Sweden where the milkers have to dip their boots in an antiseptic solution before entering the milking-shed; this may sound like a *reductio ad absurdum* but the resulting milk when bottled is bought up eagerly at 2*d*. a pint. The Dutch practice is interesting, since it abolishes the middleman in the distribution of milk, the cowkeepers forming coöperative societies to dispose of their own produce, a method which obviously facilitates the proper inspection of the cows. Mr. Douglas acknowledged the difficulties connected with the transport of milk but did not suggest the simple precaution of locking and sealing the churns, which some companies have adopted and which we have advocated strenuously for several years. The paper was an excellent little sermon in hygiene such as may bear good fruit amongst its hearers; it was thoroughly temperate in expression but we should like to know his authority for this statement, "It has also been found that 91 per cent. of the people who die are affected to a more or less degree with tuberculosis, although that may not be the immediate cause of death." Even if 91 per cent. of the subjects of all necropsies were found to are now being held at the Foreign Office, the discussion so far having been of a highly technical character.

Dr. J. Cosmo Stuart Rashleigh has been appointed sheriff of the county of Cornwall.

SANITARY REFORM IN INDIA.

III.[1]—LUNATIC ASYLUMS.

WE will next consider the reports of the lunatic asylums in India.

United Provinces of Agra and Oudh.

The triennial report of the lunatic asylums in the United Provinces of Agra and Oudh for the years 1903, 1904, and 1905, is issued by Colonel R. D. Murray, I.M.S., the Inspector-General of Civil Hospitals, United Provinces. There are four asylums for lunatics in the United Provinces—namely, those of Lucknow, Benares, Agra, and Bareilly. With regard to the number of lunatics we find that at the commencement of the year 1903 there were 1136 in the four asylums, the number rising to 1150 on Jan. 1st, 1904, and to 1183 on Jan. 1st, 1905. In respect to the mortality in these asylums it is satisfactory to note that during the triennium under notice this was much less than that of the former three years, the average percentage of which was 7·48, whilst that of the triennium which we are reviewing is seen to have shrunk to 6·29, notwithstanding that there was an increase in 1905 due to the unusual rate of sickness in Benares. The chief diseases under hospital treatment during the three years were at Agra malarial fevers which headed the list by a considerable majority, dysentery, general debility and anæmia, epilepsy and maniacal excitement, with some others of less extent. It is remarkable that not one case of tuberculosis of the lung occurred, a testimony of the ample space available. There were also no cases of suicide. No epidemic prevailed nor was there any plague and there was no overcrowding at any time. At Bareilly the chief causes of sickness were malarial fevers which again headed the list; next came pulmonary tuberculosis, diarrhœa, and dysentery in order of severity amongst the medical affections. It will be seen, therefore, that pulmonary tuberculosis prevailed somewhat largely, there being 38 cases with 16 deaths, as contrasted with the absence of any cases at Agra, one case at Lucknow, and with 15 cases at Benares, and in view of the prevalence of this disease at Bareilly the question of concreting the "kutcha" floors is to be considered. During the prevalence of plague in the city the very wise precaution was taken, in order to prevent its entry into the asylums, of inducing the attendants with their families to leave the city and to live on the asylum grounds, temporary huts being raised for those who could not be accommodated in the existing quarters. The attendants, as well as many of their families, were also inoculated.

At Benares the principal diseases were likewise malaria in large excess, while next came influenza, dysentery, pneumonia, with 15 cases of pulmonary tuberculosis. Lieutenant-Colonel T. H. Sweeny, I.M.S., who was in medical charge, remarks on the exceptional sickness and mortality in the year 1905 in this asylum, the death-rate being the third highest in the last 20 years. Nothing in it or in its arrangements seemed to account for this, either in the opinion of Lieutenant-Colonel Sweeny or of that of the Sanitary Commissioner with the Government of India. Such sickness, moreover, prevailed, not only in the jail and police lines, but also in the city and in the whole district, so that these authorities were compelled to assume that some climatic influence prevailed over the whole locality; and inasmuch as might be expected in the case of lunatics the preliminary symptoms of their maladies were not declared the mortality was naturally accentuated among them. The severe type of the malarial fever present at the beginning of the year, together with the prolonged and unhealthy hot weather, debilitated practically all the inmates. Lastly, in Lucknow we find the chief causes of sickness to be malarial fevers which once more head the list; next come cases of maniacal excitement, anæmia, diarrhœa, and dysentery. There was only one case of pulmonary tuberculosis.

During the year 1905 an important change was recommended. Agra has been for some time considered to be the most unsuitable place for the accommodation of European lunatics on account of the intense heat there for some months of the year. The construction of a central asylum for these lunatics has been under discussion for some years, the most recent proposal being that those of Upper India should be confined in an asylum to be erected either at Chindwara in the Central Provinces, or at Ranchi in Bengal. Meanwhile, it was recognised that something must be done for the European lunatics at Agra, and after carefully considering the case it was determined to make a mutual exchange, the native lunatics being moved from Lucknow to Agra, whilst the Europeans were transferred from Agra to Lucknow. A certain portion of this latter institution was altered in its structural arrangements, so that 14 rooms for males and six rooms for females were prepared. All the rooms are very large and will accommodate two patients, except in the case of those who are violent or dirty in their habits. But unfortunately, as it seems to us, this well-devised proposal was negatived by the Government of India, which has ruled that it is incompatible with the scheme for the administration of lunatic asylums in India which was sanctioned by the Secretary of State in 1900. The question of the disposal of the Lucknow asylum must therefore be again considered.

Another question raised during the year 1905 is that of the treatment of recovered criminal lunatics. This is whether, without any increased cost to the Government, accommodation apart from other lunatics and criminals could be provided for recovered criminal lunatics, and at the same time whether facilities could be provided for gradually giving them a certain amount of probationary freedom so as to test their fitness for eventual release. It is proposed to set aside a portion of the lunatic asylum at Lucknow that has been set free by the transference of native lunatics from that station to Agra and this proposal meets with the approval of the Inspector-General who, however, is doubtful as to the expediency of allowing recovered lunatics to visit the bazaar during their probationary period. He rightly, it seems to us, considers it a matter of doubt whether they could be trusted to return to their barracks at night unless escorted by a guard; and as an alternative he proposes to employ them in interesting and skilled labour within the institution, thus giving them the full benefit of regular work which would be the best means of keeping their minds in stable equilibrium.

With regard to the cures effected, the percentages of recoveries to the daily average strength of these four asylums was 10·92, 10·28, and 13·07 in 1905, 1904, and 1903 respectively. Amongst other points noted in this interesting report are the religion, sex, and places of residence of the lunatics, their previous occupation, and their ages, the largest number of admissions being between those of 20 and 40 years, and the next between 40 and 60 years. The various types of insanity are also noted, from which it appears that the greatest number of patients were admitted under the head of mania. With regard to the causes to which the insanity was attributed, the most frequent was epilepsy and next to that came charas and ganja smoking; opium smoking and eating together accounted for four cases as compared with 177 cases of the two former. Colonel Murray concludes his report with remarks on the expenditure incurred, its amount and the items accounting for it, and he accords well-deserved praise to each superintendent, which praise is endorsed by the Government of the United Provinces.

Central Provinces.

We now turn to the lunatic asylums in the Central Provinces, the report of which for the year 1906 is furnished by Colonel P. A. Weir, I.M.S. In the first place it may be noted that the daily average strength in the two asylums of these Provinces as compared with that of the year 1905 was greater in Nagpore by 7·50 and less in Jubbulpore by 2·30; in both instances the males caused the increase and the decrease, whilst the number discharged was eight in Nagpore and 13 in Jubbulpore, against 22 and 21 respectively in the previous year. The deaths numbered 25 in Nagpore and six in Jubbulpore, as contrasted with 17 and 12 in 1905, and in this is seen a considerable increase in the female mortality. The year was a comparatively unhealthy one for the Nagpore Asylum, whereas the health was generally good in Jubbulpore. As regards the classification of the lunatics, it was again these poisonous products could be distinctly detected, and if that is the case it is obvious that they may find their way into the human organism. The worst offender appears to be the match the tip of which contains phosphorus, because the whole of the phosphorus in that case is burnt, whereas in the safety match, which is generally a wooden one, there is little or no phosphorus burnt, the phosphorus, the igniting agent, being upon the rubber of the box. But the match head without phosphorus may contain lead, antimony, barium, or cyanides. It is clear from all this that the modern match, in spite of its great advance on the tinder-box, is capable of considerable improvement, especially having regard to the fact that its combustion gives rise to the formation and distribution of poisonous fumes and gases.

Algiers	62	34	60	46	53·2	14	15	2·74
Biarritz	59	34	52	42	47·3	10	20	4·30
Lisbon	63	39	59	46	52·6	13	No rain.	

* A day with at least 0·04 inch.

The most striking feature shown by the above table is the extreme dryness of the month at Nice, Lisbon, and Genoa. At Nice the absolute lack of rain is all the more remarkable because of the fact that January was also rainless. At none of the stations either at home or abroad was the period a wet one except at Biarritz, where after about a week of very fine bright weather rain was very frequent and sometimes heavy. With regard to temperature the most salient feature is certainly the extraordinary small diurnal range of only 6° at the Scilly Isles. The exact mean diurnal range was in fact only 5·6°. That ocean-surrounded spot is of course well known to be the most equable spot in the United Kingdom but last month its equability was more marked than usual. The climate over these islands generally was mild for the time of the year and it will be seen that the mean temperature at Torquay and Plymouth compares very favourably with that at Nice, Rome, and Florence, and that the mean at the last-mentioned city was exactly the same as that at Sandown, while at Scilly the mean warmth was higher than that at Biarritz and almost identical with that at Naples. As is nearly always the case, however, the resorts in Southern Europe were warmer during the day time than in this country and sunshine was also much more prevalent. On the Riviera the month was practically one with continuously blue sky and the atmosphere was very dry. Among the inland places Berlin was much the coldest, followed by Brussels, Paris, and Harrogate, while London experienced a very similar temperature to Manchester. There was no higher shade temperature than 63° even at the most southern resorts of the Mediterranean, but after February the warmth of the days increases quickly in that region, and it is probable that before March comes to an end the thermometer will record readings some way above 70°.

OPHTHALMOLOGY AT OXFORD.

THE fourth annual post-graduate course in ophthalmology in connexion with the Faculty of Medicine of the University of Oxford will be held at the Oxford Eye Hospital and at the Radcliffe Infirmary between July 15th and 27th, the last two days of which will be made the occasion of a small congress of ophthalmologists and of the demonstration of many interesting cases and methods. The course itself is to be a very complete one and by no means a "holiday class," for the syllabus shows a solid eight hour a day programme and has been arranged with a view to afford so far as possible the complete practical illustration of a systematic text-book of ophthalmology. No less than 500 cases are promised for demonstration and we doubt if even the clinical material of a large eye hospital could afford so complete a scheme of instruction without a considerable amount of "arranging." Such is being done thoroughly at Oxford and both the University and the Eye Hospital are to be congratulated on working together to secure this result. Medical men attending the congress will be provided with quarters and meals at Keble College for 7*s.* 6*d.* per diem and the syllabus of the course, with all other information, can be obtained from the Margaret Ogilvie Reader in Ophthalmology, Mr. R. W. Doyne, 34, Weymouth-street, London, W., who is senior surgeon to the Oxford Eye Hospital and who will be associated in the conduct of the course with other well-known teachers. The last report of the Oxford Eye Hospital, which is able to draw ample clinical material from the surrounding countryside, is a record of excellent work.

YOUNG SMOKERS.

OUR Manchester correspondent writes: "Meetings were held in Manchester on Feb. 20th of the British Anti-Tobacco and Anti-Narcotic League. It was an occasion of rejoicing to the members who are delighted at the introduction of the Children's Bill. Its drastic clauses prohibiting young people under 16 years of age from buying tobacco or smoking in public places are very pleasing to them. Most of us, even the hardened and unrepentant smokers, whether slaves to the vice or so far masters of themselves as to fill a pipe or put it down with equanimity, will be of the same mind as to the ill-effects of juvenile smoking. The report expressed great satisfaction at the action of the Government. No doubt there are young people in shoals who are given to smoking in public or in private. In days gone by, too far back with some of us, the forbidden pleasure was indulged in with the most modest care as to privacy. There was then no flaunting of cheap cigarettes in the public streets, or even of the piece of cane that was often used as a substitute. It is so far satisfactory to know that in the Manchester district there are,

are now being held at the Foreign Office, the discussion so far having been of a highly technical character.

Dr. J. Cosmo Stuart Rashleigh has been appointed sheriff of the county of Cornwall.

SANITARY REFORM IN INDIA.

III.[1]—LUNATIC ASYLUMS.

WE will next consider the reports of the lunatic asylums in India.

United Provinces of Agra and Oudh.

The triennial report of the lunatic asylums in the United Provinces of Agra and Oudh for the years 1903, 1904, and 1905, is issued by Colonel R. D. Murray, I.M.S., the Inspector-General of Civil Hospitals, United Provinces. There are four asylums for lunatics in the United Provinces—namely, those of Lucknow, Benares, Agra, and Bareilly. With regard to the number of lunatics we find that at the commencement of the year 1903 there were 1136 in the four asylums, the number rising to 1150 on Jan. 1st, 1904, and to 1183 on Jan. 1st, 1905. In respect to the mortality in these asylums it is satisfactory to note that during the triennium under notice this was much less than that of the former three years, the average percentage of which was 7·48, whilst that of the triennium which we are reviewing is seen to have shrunk to 6·29, notwithstanding that there was an increase in 1905 due to the unusual rate of sickness in Benares. The chief diseases under hospital treatment during the three years were at Agra malarial fevers which headed the list by a considerable majority, dysentery, general debility and anæmia, epilepsy and maniacal excitement, with some others of less extent. It is remarkable that not one case of tuberculosis of the lung occurred, a testimony of the ample space available. There were also no cases of suicide. No epidemic prevailed nor was there any plague and there was no overcrowding at any time. At Bareilly the chief causes of sickness were malarial fevers which again headed the list; next came pulmonary tuberculosis, diarrhœa, and dysentery in order of severity amongst the medical affections. It will be seen, therefore, that pulmonary tuberculosis prevailed somewhat largely, there being 38 cases with 16 deaths, as contrasted with the absence of any cases at Agra, one case at Lucknow, and with 15 cases at Benares, and in view of the prevalence of this disease at Bareilly the question of concreting the "kutcha" floors is to be considered. During the prevalence of plague in the city the very wise precaution was taken, in order to prevent its entry into the asylums, of inducing the attendants with their families to leave the city and to live on the asylum grounds, temporary huts being raised for those who could not be accommodated in the existing quarters. The attendants, as well as many of their families, were also inoculated.

At Benares the principal diseases were likewise malaria in large excess, while next came influenza, dysentery, pneumonia, with 15 cases of pulmonary tuberculosis. Lieutenant-Colonel T. H. Sweeny, I.M.S., who was in medical charge, remarks on the exceptional sickness and mortality in the year 1905 in this asylum, the death-rate being the third highest in the last 20 years. Nothing in it or in its arrangements seemed to account for this, either in the opinion of Lieutenant-Colonel Sweeny or of that of the Sanitary Commissioner with the Government of India. Such sickness, moreover, prevailed, not only in the jail and police lines, but also in the city and in the whole district, so that these authorities were compelled to assume that some climatic influence prevailed over the whole locality; and inasmuch as might be expected in the case of lunatics the preliminary symptoms of their maladies were not declared the mortality was naturally accentuated among them. The severe type of the malarial fever present at the beginning of the year, together with the prolonged and unhealthy hot weather, debilitated practically all the inmates. Lastly, in Lucknow we find the chief causes of sickness to be malarial fevers which once more head the list; next come cases of maniacal excitement, anæmia, diarrhœa, and dysentery. There was only one case of pulmonary tuberculosis.

During the year 1905 an important change was recommended. Agra has been for some time considered to be the most unsuitable place for the accommodation of European lunatics on account of the intense heat there for some months of the year. The construction of a central asylum for these lunatics has been under discussion for some years, the most recent proposal being that those of Upper India should be confined in an asylum to be erected either at Chindwara in the Central Provinces, or at Ranchi in Bengal. Meanwhile, it was recognised that something must be done for the European lunatics at Agra, and after carefully considering the case it was determined to make a mutual exchange, the native lunatics being moved from Lucknow to Agra, whilst the Europeans were transferred from Agra to Lucknow. A certain portion of this latter institution was altered in its structural arrangements, so that 14 rooms for males and six rooms for females were prepared. All the rooms are very large and will accommodate two patients, except in the case of those who are violent or dirty in their habits. But unfortunately, as it seems to us, this well-devised proposal was negatived by the Government of India, which has ruled that it is incompatible with the scheme for the administration of lunatic asylums in India which was sanctioned by the Secretary of State in 1900. The question of the disposal of the Lucknow asylum must therefore be again considered.

Another question raised during the year 1905 is that of the treatment of recovered criminal lunatics. This is whether, without any increased cost to the Government, accommodation apart from other lunatics and criminals could be provided for recovered criminal lunatics, and at the same time whether facilities could be provided for gradually giving them a certain amount of probationary freedom so as to test their fitness for eventual release. It is proposed to set aside a portion of the lunatic asylum at Lucknow that has been set free by the transference of native lunatics from that station to Agra and this proposal meets with the approval of the Inspector-General who, however, is doubtful as to the expediency of allowing recovered lunatics to visit the bazaar during their probationary period. He rightly, it seems to us, considers it a matter of doubt whether they could be trusted to return to their barracks at night unless escorted by a guard; and as an alternative he proposes to employ them in interesting and skilled labour within the institution, thus giving them the full benefit of regular work which would be the best means of keeping their minds in stable equilibrium.

With regard to the cures effected, the percentages of recoveries to the daily average strength of these four asylums was 10·92, 10·28, and 13·07 in 1905, 1904, and 1903 respectively. Amongst other points noted in this interesting report are the religion, sex, and places of residence of the lunatics, their previous occupation, and their ages, the largest number of admissions being between those of 20 and 40 years, and the next between 40 and 60 years. The various types of insanity are also noted, from which it appears that the greatest number of patients were admitted under the head of mania. With regard to the causes to which the insanity was attributed, the most frequent was epilepsy and next to that came charas and ganja smoking; opium smoking and eating together accounted for four cases as compared with 177 cases of the two former. Colonel Murray concludes his report with remarks on the expenditure incurred, its amount and the items accounting for it, and he accords well-deserved praise to each superintendent, which praise is endorsed by the Government of the United Provinces.

Central Provinces.

We now turn to the lunatic asylums in the Central Provinces, the report of which for the year 1906 is furnished by Colonel P. A. Weir, I.M.S. In the first place it may be noted that the daily average strength in the two asylums of these Provinces as compared with that of the year 1905 was greater in Nagpore by 7·50 and less in Jubbulpore by 2·30; in both instances the males caused the increase and the decrease, whilst the number discharged was eight in Nagpore and 13 in Jubbulpore, against 22 and 21 respectively in the previous year. The deaths numbered 25 in Nagpore and six in Jubbulpore, as contrasted with 17 and 12 in 1905, and in this is seen a considerable increase in the female mortality. The year was a comparatively unhealthy one for the Nagpore Asylum, whereas the health was generally good in Jubbulpore. As regards the classification of the lunatics, it was again while the right lateral aspect tends to become more anterior in position. The explanation offered of these changes depends upon the anatomical relations of the arch of the aorta to the left bronchus and to the trachea. The left bronchus may be pushed *downwards and to the left by an* aneurysm of the concavity of the arch of the aorta; the left bronchus then draws upon the trachea and this in turn upon the larynx. The deviation and torsion produced in this manner are not very marked, but if the aneurysm continues to grow to the left the bronchus becomes fixed, further traction is made upon the trachea, displacing it more to the left at the same time, the total result on the larynx being that it is drawn downwards, backwards, and to the left.

---

[1] Nos. I. and II. were published in THE LANCET of Feb. 22nd (p. 582) and 29th (p. 661), 1908, respectively

KING EDWARD'S HOSPITAL FUND FOR LONDON

WE are asked to state that hospitals in the county of London, or within nine miles of Charing Cross, desiring to participate in the grants made by this Fund for the year 1908 must make application before March 25th to the honorary secretaries, 7, Walbrook, E.C. Applications will also be considered from convalescent homes and sanatoriums for consumption which are situated within the above boundaries or which being situated outside take a large proportion of patients from London. It will be seen that the scope of the operations of the Fund has been extended by the enlargement of the radius from seven to nine miles from Charing Cross as well as by the admission to consideration of the claims of sanatoriums for consumption situated in the country in those cases in which it can be shown that a large number of London patients are treated.

THE TREATMENT OF CHLOASMA, FRECKLES, AND OTHER PIGMENTATIONS BY SCARIFICATION AND APPLICATION OF OXYGENATED WATER.

AT a meeting of the Société Médicale des Hôpitaux of Paris on Feb. 14th M. Masotti described a new method of treating chloasma, freckles, and other pigmentations—scarification followed by the application of oxygenated water—which he had found most successful. In scarifying a patient suffering from acne complicated by chloasma he found to his surprise that after a few sittings the chloasma disappeared. This suggested to him the use of scarification in the treatment of pigmentation. He followed the procedure by the application to the wounds of oxygen, which has a decolourising action. Every five days fine scarifications are made very close together on the spot which it is desired to remove. The part is then washed with warm water and a tampon of cotton-wool soaked in oxygenated water is bandaged on. On the following day erythema is produced and in some days slight desquamation. The pigmentation rapidly disappears, which M. Masotti ascribes to a double action. The scarification causes prompt renovation of the epidermis and the oxygen is brought into direct contact with the pigment on which it exercises its strongly decolourising effect. This method has a great advantage over others that have been employed for the same purpose; it does not produce pain or irritation. The 1 per cent. solution of perchloride of mercury in alcohol recommended by Kaposi causes much pain and produces blisters which have to be dressed. M. Masotti has treated with rapid success several patients suffering from chloasma and various other forms of pigmentation. Sometimes the pigmentation recurred after it had been removed. A relapse is not astonishing, for chloasma often depends on the general health of the patient and upon such conditions as anæmia, tuberculosis, uterine troubles, and so on. Hence it is necessary to combine general with local treatment. At the meeting of the society M. Masotti showed a woman in whom chloasma had disappeared under his treatment after three sittings.

THE LOCALISATION OF ARSENIC IN THE BODY.

IN the *Bulletin de la Société de Pharmacie de Bordeaux* M. Barthe communicates the results of his experiments on the localisation of arsenic in the body after the ingestion of poisonous doses. In a case of acute poisoning by arsenious acid, in which death occurred ten hours after ingestion of the poison, the following results were obtained, the figures representing milligrammes of arsenious acid per kilogramme of organ: stomach, 2003; intestines, 750; liver, 213; blood, 142; lungs, 133; kidneys, 27; muscles, 16; and brain, 2. Several other investigators have obtained similar results, showing the absence of arsenic from the nerve centres, though Scolosuboff held the opinion that large proportions of the poison were absorbed by the nerve centres in cases of poisoning by arsenic.

THE INCOMPATIBILITIES OF ORGANIC SALTS OF SILVER.

IN the *Répertoire de Pharmacie* Dr. V. Demandre deals with various substances which are incompatible with argyrol (silver protein). Argyrol is decomposed by light and is attacked by hydrochloric acid. Alkaline chlorides yield with argyrol a precipitate of silver chloride. The hydrochloride of pilocarpine should never be prescribed with argyrol owing to the formation of a brown precipitate; the nitrate of pilocarpine, however, does not decompose argyrol. The addition of adrenalin to argyrol in solution leads to similar changes to those produced in the case of hydrochloric acid. Cocaine hydrochloride in solution is immediately and completely decomposed by argyrol and the same result is obtained with the sulphates of copper and zinc. Argyrol is decomposed by several other compounds, including the hydrochlorides of morphine, heroin, quinine, cinchonine, and sparteine. Both argyrol and protargol may be prescribed with the hydrochlorides of cocaine, tropacocaine, alpha eucaine, holocaine, and neroanine if these substances are dissolved in a 1·5 per cent. aqueous solution of boric acid. These observations respecting two of the important organic compounds of silver will probably be found useful in the case of others of this class.

THE President of the Local Government Board has authorised for the current year the following researches, in addition to those already announced, under the grant voted by Parliament in aid of scientific investigations concerning the causes and processes of disease: 1. Further studies by Dr. F. W. Andrewes and Dr. T. J. Horder as to methods of inhibiting in the animal body the activities of infection by certain cocci. 2. A study of the various forms of pneumonia, especially in children, by Mr. A. G. R. Foulerton. 3. A study of acid-fast bacilli in butter by Dr. D. N. Nabarro. 4. An investigation of the injurious gases evolved during artificial illumination by Dr. J. Wade, D.Sc.

THE annual meeting and dinner of the Irish Medical Schools' and Graduates' Association will be held at the Hotel Great Central on March 17th, St. Patrick's Day; Surgeon-General Sir Charles Cuffe, K.C.B., the President, will preside. The Right Hon. Sir Edward H. Carson, P.C., K.C., and Professor B. C. A. Windle, F.R.S., President of Queen's College, Cork, will be guests of the association.

THE Department of Public Health of Queensland in a bulletin dated Feb. 1st states that on Jan. 23rd a case of plague was reported at Cairns. The patient died on Jan. 29th.

MEETINGS of the International Sleeping Sickness Conference summoned by midwives the latter will frequently be unable to obtain medical assistance. It is apparently the more galling to medical practitioners to be called on to assist midwives in difficult emergencies without payment, because they often regard the midwives as competing with them for midwifery practice, and doing so with the advantage of charging lower fees, and of being able to advertise for patients with impunity.

This committee is of opinion that the Poor-law guardians, or other competent authority, should arrange for the payment of medical practitioners summoned by midwives to assist them in emergencies, and the committee considers that the scale of payment should, in any case, not be lower than the existing Poor-law scale for attendance on midwifery cases. While present conditions continue the committee recommends medical men to require payment to be made in advance or guaranteed by some responsible person.

Signed on behalf of the committee,

31st January, 1908. G. A. HERON, Chairman.

The London and Counties Medical Protection Society has done good work in thus prominently bringing before the profession the difficult and disagreeable position of the medical practitioner under the Midwives Act.

THE CITY OF GLASGOW FEVER HOSPITAL AT RUCHILL.

OUR Glasgow correspondent in his letter published in THE LANCET of Feb. 8th gave an outline of the administrative and other difficulties which had arisen in the City of Glasgow Fever Hospital at Ruchill. His account indicated the existence of a deplorable state of affairs, and the Scottish Local Government Board had already ordered an inquiry. The commissioners appointed for this purpose were Mr. Donald Crawford, K.C., sheriff of Aberdeen, Kincardine, and Banff; Professor H. Harvey Littlejohn, of the University of Edinburgh; and Mr. A. Murray, chief clerk to the Local Government Board—men whose acknowledged ability could not fail to give great weight to their collective opinions. The commissioners describe their proceedings as "a public inquiry into the complaints of overcrowding and under-staffing of the Ruchill Fever Hospital and on its administration and management." The inquiry was held in Glasgow on Feb. 3rd and the four following days and the commissioners' report has been issued with commendable promptitude in the form of an eight-page pamphlet.[1] We have no hesitation in saying that the report deserves the careful attention of the medical men in charge of large isolation hospitals because it illustrates only too well how certain evils have been allowed to seethe and simmer unchecked till at last they suddenly frothed up and boiled over. The commissioners arranged their observations under the four heads of overcrowding, under-staffing, friction within the hospital, and responsibility for overcrowding. There was no doubt about the overcrowding, for the hospital was constructed to accommodate 440 patients, but in December, 1907, on some days there were in the wards more than 800 patients, the majority of whom seem to have suffered from measles, although the distribution of the several diseases under treatment is not expressly stated. Of course, the remedy for this was to reduce the admissions and in seeking the culprit the commissioners solve the difficulty by blaming both the medical superintendent and the medical officer of health. In the questions of under-staffing and friction within the hospital the matron seems to play the leading part. On the subject of the authority possessed by her the commissioners say "the staffing of the hospital is the duty of the matron." It does not appear that the medical superintendent complained to her of the insufficient number of nurses but the resident medical officers did so. On Sept. 24th, while the medical superintendent was absent on a holiday, one of them spoke to her on the subject. A portion of this interview and the incidents which grew out of it are described in the report as follows:—

> He says that she replied that that was a matter with which the doctors had nothing to do, that she did not intend to get any more nurses, and that she knew she had the support of the committee in this matter. The matron's account is that Dr. Mackenzie indicated to her that if she did not come to some arrangement with the resident medical officers in regard to the staffing of the wards they were going to make a formal complaint to the hospitals committee.
>
> In seeking to raise the general question of under-staffing with the matron in the absence of the physician superintendent, we think that Dr. Mackenzie and his colleagues, if they were cognisant of it, made a serious mistake. They should have addressed themselves to their own chief. ...... The matron was not unnaturally displeased at this action by the assistant doctors but her resentment led her to make an even more serious mistake. Instead of waiting for Dr. Johnston's return the next day and complaining to him she went into the city and complained to Mr. Anderson, the convener [*Anglice*, chairman] of the hospitals committee. He had never had any communication with the matron before and had not interfered in any way with the internal management. ...... It was arranged that she should speak to the nurses and that Dr. Johnston should speak to his assistants.
>
> Accordingly the matron called the sisters together and addressed them on the 27th September, and she addressed the remaining nurses in similar terms on the 28th. ...... Miss Landles was evidently very angry. ...... The nurses' lunch, a cup of tea and bread-and-butter, between their breakfast at 6.30 and dinner at 12.30, was stopped. They were forbidden on pain of instant dismissal to give information about the nursing arrangements to the doctors. ...... Ultimately the assistant physicians and the matron were not on speaking terms. It was impossible for both to remain in the hospital together, and ...... the hospitals committee directed the physician superintendent to dismiss three of the doctors.
>
> It was officially stated to us that in dismissing the doctors the hospitals committee did not intend to cast any imputation upon their personal character or their professional ability, and this inquiry has shown that there is no room for reflection upon them in those respects, and that their complaint, in conjunction with their colleagues, to the Local Government Board as to overcrowding and under-staffing was well founded.

We congratulate the resident medical officers on the justice of their cause which has now been substantiated, and we shall be glad to hear what amends the corporation of Glasgow proposes to make for their dismissal.

MEDICINE AND THE LAW.

An Offence under the Lunacy Act, 1890.

Dr. L. S. Forbes Winslow was indicted at the recent Middlesex sessions for that he "did unlawfully aid, abet, counsel, and procure Edith Mary Lascelles to receive for payment at her house, unlicensed under the Lunacy Act, 1890, a certain lunatic, to wit, Ethel May Davis." At the same time Edith Mary Lascelles was indicted for "receiving payment to board, lodge, and detain Ethel May Davis, a lunatic, in a house not duly licensed for the purpose." A question was raised as to whether it was open to the defendants to show that they were not aware that Miss Davis was insane, but the chairman pointed out that it had been decided that ignorance was no defence to the charge, and they both withdrew their pleas of not guilty, pleading guilty to the first count of the indictment. The case, as stated by counsel representing the Public Prosecutor, showed that the male defendant had long been acquainted with the female defendant, that she had before had charge of insane persons, and that the male defendant had had ample opportunity for ascertaining the mental condition of the patient. With regard to the suggested defence of ignorance of Miss Davis's condition it was pointed out that the male defendant had frequently given evidence in courts of law in the capacity of an expert in mental disorders. With regard to the female defendant it was stated that the mother of the lunatic had complained of the dirty state in which she was allowed to be and that on one occasion the female defendant was too drunk to sign a receipt for a payment made to her by the mother. Her reply, when the complaint as to cleanliness was made, had been, "Do you expect her to be kept clean for a guinea a week?" Dr. L. S. Forbes Winslow was fined £50 and Edith Mary Lascelles was fined £10.

What is Vinegar?

An annotation under the above heading in THE LANCET of Feb. 22nd, p. 577, referred to the misdescription and adulteration of vinegar and indicated the definitions and regulations desirable in order to prevent the deception at present frequently practised on the public. Two cases recently heard at the Mansion House police-court illustrate the manner in which those who desire malt vinegar may fail to obtain that for which they ask. In the first, in which an oil- and colour-man named Missildine was the defendant, it was proved that malt vinegar had been asked for and that acetic acid diluted with water had been received, the price asked for it being at the rate of 1s. 4d. per gallon. The defendant urged in his favour that the wrong vinegar had been supplied through the mistake of his manager who was deaf and who should have known that his employer only kept malt vinegar for sale in bottles, whereas he had sold the diluted acetic acid by measure. A fine of £5 with 18s. 6d. costs was imposed. The second case resembled the first in that acetic acid and water had been sold as malt vinegar, the proportion of the acid being larger than in the first instance. The fact that two purchases had been made with the same found necessary to re-classify them; as had previously been the case in 1900, the most frequent type was mania and then came dementia, melancholia, and idiocy in the above order. With respect to the alleged causes of insanity ganja smoking was noted in 32 of the cases; opium smoking did not give a single case but opium eating accounted for two cases. With regard to the expenditure incurred, the average cost per head was Rs.11 less than in the previous year in Nagpore, and Rs.2 more per head than in 1905 in Jubbulpore. The report also shows, amongst other items, the religion, sex, and places of residence of the patients and their previous occupation. The age most affected was that between 20 and 40 years.

---

Rangoon.

A note on the Rangoon Lunatic Asylum for the year 1906 is furnished by Colonel W. G. King, I.M.S., the Inspector-General of Civil Hospitals of Burma. Here there was an increase of 27 inmates on the last day of the year 1906 as compared with that of 1905, there being 493 in 1906 as against 466 in 1905. The total accommodation provided at the small rate of 50 superficial feet per head suffices only for 429, so that there is considerable overcrowding which was confined to the criminal and female sections of the asylum. In the absence of increased and more suitable accommodation contemplated by the erection of a new asylum it was ultimately found necessary to arrange for the transfer of criminal lunatics to the disused jail at Minbu and the necessary structural arrangements were undertaken in the latter months of the year, so that it was hoped during 1907 to effect a relief to the present undesirable conditions by causing a transfer of at least 80 criminal lunatics. With regard to the overcrowding of female lunatics, a dilapidated building in the existing asylum has been sufficiently restored to permit of its use for 12 inmates. During the year an effort was made to ascertain whether it was possible to board harmless lunatics with private persons, under occasional medical supervision, and the results were favourable to this course. Much attention has been paid to the water-supply, where there were obviously possibilities of gross pollution owing to faulty methods of lifting. A "safety elevator" was purchased and worked efficiently. The trenches were removed farther from the possible drainage zone and two filters of six Berkefeld candles each, worked by pressure under hand-pumps, have been put in use during 11 months of the year. The result has been extremely satisfactory, the rate of admission for "bowel affections" in 1906 being 53·23 per 1000, as contrasted with that of 158·80 per 1000 in 1905.

Much forethought has been exercised over the details of the proposed new asylum, Lieutenant-Colonel G. J. H. Bell, I.M.S., having been deputed to visit India for the purpose of examining the different methods of administration and the structural details of the asylums there, so that any points of value might be available for the internal economy of the building. In the meantime the Department of Public Works is to modify certain wards in the existing asylum so as to arrive at a definite opinion as to various details connected with the comfort, supervision, and safe custody of severe cases of lunacy. With regard to the diet, which is entirely vegetable, Colonel King is trying to secure from China soybeans, the typical bean for the diet, for purposes of cultivation in the asylum. Respecting the death-rate, this was the lowest on record during the last ten years with the exception of that for the year 1900. The daily average of sick was 31·07 of the strength, against 31·69 of the previous year 1905. Malarial fevers only accounted for nine cases. Beri-beri gave one case which was imported, but there was naturally some anxiety as to the spread of this disease owing to the overcrowded state of the asylum. This fortunately did not, however, occur. Tuberculosis caused six deaths in 1906, an increase over 1905, in which year there were only two cases admitted. With reference to the various types of insanity admitted we find that mania headed the list, followed by melancholia, and then dementia.

Lastly, respecting the expenditure, this increased per head of average strength per annum from Rs.149 7a. 5p. in 1905 to Rs.158 8a. 3p. in 1906, whilst the total expenditure in 1906 was Rs.75,293, against Rs.67,855 in 1905. This increase was due to the fact that the full staff sanctioned by the Government of Burma in 1905 was entertained. It is, however, gratifying to note that there was a material saving of Rs.2 14a. 4p. per head under "contingencies," an item under which if supervision be not careful much extravagance may result. Had, in fact, the cost of the establishment been the same as during the preceding year, the total cost per head for 1906 would have been Rs.143 5a. 3p., against Rs.149 7a. 5p. in the preceding year. A net profit in 1906 under manufactures of Rs.14,165, as against Rs.1,21,836 in 1905, together with a decline of injuries from 6·39 per cent. of average strength in 1905 to 2·74 in 1906, certainly imply a better grade of supervision by this increased staff. This so-called "Note" is a model of what a report should be; all the facts are set forth in a concise, readable form, such as would be expected from an officer of Colonel King's well-deserved reputation.

BRITISH MEDICAL BENEVOLENT FUND.

AT the February meeting eight applications were received and grants amounting to £94 were voted in relief. The following is an abstract of the cases:—

Daughter, aged 53 years, of late L.F.P.S. Glasg. Only income £10 a year from a charity and is unable to make any effort at self-support owing to ill-health. Relieved once, £12. Voted £12 in 12 instalments.

Widow, aged 65 years, of M.D. Aberd. No income. Earns a little by sewing. Children unable to help. Relieved seven times, £90. Voted £12 in 12 instalments.

Daughter, aged 55 years, of late L.S.A. No income. Lets rooms, but finds difficulty in getting lodgers and has been obliged to sell most of her furniture. Voted £10 in ten instalments.

Widow, aged 46 years, of M.B. Durh., M.R.C.S. Eng. No income; endeavours to support herself by letting lodgings. Two children, aged 16 and 14 years. Voted £12 in 12 instalments.

Widow, aged 59 years, of L.R.C.P., L.R.C.S. Irel. Was provided for at husband's death, but lost everything through the failure of a bank a little more than a year ago. Slight help from a sister who earns a living as companion. Relieved once, £12. Voted £12 in 12 instalments.

Daughter, aged 62 years, of late M.R.C.S., L.S.A. Maintained herself for many years but is now deaf and in indifferent health and unable to get work. No income; a friend pays the rent of a room. Relieved nine times, £103. Voted £12 in 12 instalments.

Widow, aged 44 years, of M.D. R.U.I. Quite unprovided for at husband's sudden death some years ago and now acts as housekeeper, receiving a home for herself and only child in exchange for her services. Relieved nine times, £107. Voted £12 in 12 instalments.

Daughter, aged 65 years, of late M.D. Edin. Supported herself until nearly 60 years old, but for the last few years has had to live with an aged mother, an annuitant of this fund. Applicant has recently been operated upon for new growth. Relieved four times, £24. Voted £12 in 12 instalments.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY AND THE MIDWIVES QUESTION.

THE following is the report of the Midwives Committee of this society, which has received the unanimous approval of the council of the society:—

This committee was appointed for the purpose of considering the working of the Midwives Act, and reporting thereon, especially in reference to the remuneration of medical practitioners called in by midwives.

The committee accordingly directed that a circular letter should be addressed to members of the society, and other medical practitioners, and also published in the medical press, asking for (1) information as to the number of confinements to which each medical practitioner had been summoned by midwives under the regulations of the Midwives' Board; (2) what payment they had received in each case, and from whom; (3) and what was the nature of each case to which they were summoned.

Several hundred replies were received, and the following information has been derived from them:—

A large number of practitioners replied saying that they had never been summoned by midwives, several saying that there were no midwives in their districts.

In considerably more than half the cases the medical practitioners summoned by midwives received no payment whatever, and the average payment, calculated from a large number of cases, was not over 9*s*. A noteworthy point is that while some practitioners seem to be uniformly unpaid a few seem to be almost uniformly paid. Probably the class of people in the districts concerned accounts largely for this; but, in one or two instances, the explanation given by the medical practitioner was that he refused to go unless paid.

Of the fees received all but a few were received from the patients or their relatives, and it seems to be quite exceptional for payment to be made by the midwife. A few fees were paid by boards of guardians, nursing associations, provident dispensaries, &c.

The cases to which the medical practitioners were summoned were in the great majority serious ones. Operative assistance was required in many cases. The largest number of the less serious cases were described as delayed or difficult labour. In about 3 per cent. of the cases the death of the child appears to have been the cause of the summoning of the doctor, and puerperal fever was the cause in about 2 per cent. of the cases.

Grave dissatisfaction was expressed by many of the writers at the present state of affairs, and it is evident from the tone of many of the letters that unless proper provision is made for the payment of doctors not certified or not stated; in the 76 English towns the proportion of uncertified deaths in the same week did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 25·5 and 21·0 per 1000 in the two preceding weeks, rose again to 24·1 in the week ending March 7th. During the first ten weeks of the current quarter the death-rate in the city averaged 25·5 per 1000, the mean rates during the same period being only 17·9 in London and 18·9 in Edinburgh. The 182 deaths of Dublin residents registered in the week under notice showed an increase of 23 upon the number in the previous week, and included nine which were referred to the principal epidemic diseases, against four and seven in the two preceding weeks; these nine deaths included three from diphtheria, two from whooping-cough, two from diarrhœa, and one each from scarlet fever and "fever," but not one either from measles or small-pox. These nine deaths were equal to an annual rate of 1·2 per 1000, the death-rate last week from these principal epidemic diseases being also equal to 1·2 in London and 1·6 in Edinburgh. The three fatal cases of diphtheria exceeded the number in any previous week of this year. The 182 deaths from all causes in Dublin last week included 33 of infants under one year of age and 53 of persons aged upwards of 60 years. Nine inquest cases and eight deaths from violence were registered, and 68, or 37·3 per cent., of the deaths occurred in public institutions. The causes of 12, or 6·6 per cent., of the deaths in Dublin last week were not certified; in London all but one of the 1580 deaths registered were duly certified, while in Edinburgh the proportion of uncertified deaths was 3·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon: J. C. Ferguson to the *Duke of Edinburgh*, on recommissioning. Staff Surgeon: W. H. C. Garde to the *Victory*, additional, to be lent to Haslar Hospital. Surgeons: H. G. T. Major to the *Donegal;* G. Price to the *Vivid*, additional, to be lent to the *Circe*, temporary; T. A. Smyth to the *Research;* A. J. Wernet to the *Canopus;* W. G. Edwards to Plymouth Hospital; A. B. Marsh lent to the *Hebe*, temporary; A. C. Renwick to the *Pembroke*, additional, to be lent to the *Jason*, temporary; H. M. Langdale to the *Spanker*, lent, temporary, appointment to the *Shannon* cancelled; R. R. Horley to the *Duke of Edinburgh*, on recommissioning; and L. C. E. Murphy to the *Vernon*, additional, for the *Furious*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Herbert E. R. James retires on retired pay (dated March 7th, 1908).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st West Riding of Yorkshire: Surgeon-Captain P. J. S. Bird resigns his commission (dated Jan. 28th, 1908). 1st Carnarvonshire: Surgeon-Lieutenant C. W. Owen resigns his commission and is appointed Second Lieutenant (dated Feb. 17th, 1908). 6th Lancashire: Surgeon-Captain W. T. Blackledge resigns his commission and is appointed Captain (dated Feb. 18th, 1908).

Royal Engineers (Volunteers): 1st London: Surgeon-Captain E. C. Roberts resigns his commission (dated Feb. 20th, 1908).

Rifle: 2nd Volunteer Battalion, The Welsh Regiment: Surgeon-Lieutenant-Colonel D. Hepburn is granted the honorary rank of Surgeon-Colonel (dated Feb. 12th, 1908). 24th Middlesex Volunteer Rifle Corps: Surgeon-Captain C. Graham Grant to be Surgeon-Major (dated Jan. 31st, 1908).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

London District (London Companies): Lieutenant-Colonel and Honorary Colonel V. Matthews resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated Feb. 17th, 1908); Major J. Harper to be Lieutenant-Colonel and is appointed to command the companies under the conditions of Paragraph 47 of the Volunteer Regulations (dated Feb. 17th, 1908); Captain J. R. Whait to be Major (dated Feb. 17th, 1908). South Wales Border Bearer Company: Lieutenant John O'Sullivan, from the Manchester Companies, to be Lieutenant (dated Dec. 19th, 1907).

A dinner of past and present members of the London companies will be held at the Holborn Restaurant (Venetian Hall) on Tuesday, March 31st, at 7.30 P.M. This date has been fixed in order that the corps may fittingly mark the close of the twenty-third year of its embodiment, prior to being merged in the Territorial Force. There will be no other guests than past members. Tickets at the price of 3*s.* 6*d.* each (exclusive of wines, &c.) can be obtained from the honorary secretaries, Regl. Quarter-Master-Sergeant Bell, Headquarters, 51, Calthorpe-street, Gray's Inn-road, London, W.C., and Sergeant May, Elmhurst, East Sheen, London, S.W.

THE TERRITORIAL FORCE.

Colonel J. Turton, R.A.M.C. (Vols.), V.D., Senior Medical Officer of the Sussex and Kent Volunteer Infantry Brigade, is to be appointed Principal Medical Officer of the Home Counties Division of the Territorial Force. Surgeon-Colonel G. S. Elliston, V.D., Senior Medical Officer, Suffolk Volunteer Infantry Brigade, has been appointed Principal Medical Officer of the East Anglian Division of the Territorial Force. Surgeon-Colonel J. Raglan Thomas, Senior Medical Officer, Devon Volunteer Infantry Brigade, has been appointed Principal Medical Officer of the Wessex Division of the Territorial Force.

VOLUNTEER SURGEONS.

In the House of Commons on March 5th, Mr. Haldane, in reply to Sir F. Powell, said that medical officers of the Volunteers will have the option of transferring to the Royal Territorial Medical Corps or of remaining regimental officers. Those who transfer will be permitted to retain the uniform of their former unit until worn out. The compound title will be abolished in the case of those who join the Territorial Medical Corps. The appointment of brigade-surgeon in the Territorial Force will lapse, as the Territorial Force will be organised on the same basis as the Regular Army, in which such appointment does not exist.

TUBERCULOSIS IN THE ARMY.

The preliminary report of the War Office committee appointed to consider the care and treatment after discharge from the army of soldiers invalided for tuberculous disease shows that the committee is of opinion that the practicable methods of treatment resolve themselves into the following:—

(*a*) To continue the present method—viz., to discharge at once from the army any man who is diagnosed as suffering from tubercle of the lung, to discharge him from hospital as soon as he is fit to travel, and afterwards to disown all responsibility for him.

(*b*) To provide a special central military sanatorium for tuberculous patients to which all soldiers suffering from the disease should be sent for treatment.

(*c*) To make use of existing civil sanatoria in all parts of the country by reserving in each a number of beds at the expense of army funds, and by transferring soldiers who are suspected of having the disease to the available institution nearest to their own homes.

The committee recommends the last of the three suggestions. We shall take the suggestions into full consideration at an early opportunity.

Surgeon-Major Caspar Robert Laurie, A.M.R., has been promoted from Honorary Associate to Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England.

METROPOLITAN CONVALESCENT INSTITUTION.—The sixty-eighth annual meeting of the governors of this association was held at Sackville-street, W., on March 3rd, Mr. M. C. FitzGerald being in the chair. The annual report stated that the number of patients admitted to the four homes in 1907 was 7515. Reference was made to the arrangements that had been made for the reception of patients requiring treatment after surgical operation in specially equipped wards at the Bexhill and Little Common homes with the object of relieving the great pressure upon the surgical beds at hospitals by receiving patients in an early stage of convalescence. Since the scheme was inaugurated in June, 1906, 311 patients had occupied beds in the surgical wards. Last year 207 cases were treated, the number which would be termed major operation cases being 87. The income of the institution in 1907 was £13,031 and the expenditure £14,228. As a result of a shortage of income in the last two years, due mainly to a falling off in the receipts from legacies, there is now a deficit of £2678 and an earnest appeal is made for this amount. The report was adopted and the proceedings terminated with the usual formal votes of thanks.

found necessary to re-classify them; as had previously been the case in 1900, the most frequent type was mania and then came dementia, melancholia, and idiocy in the above order. With respect to the alleged causes of insanity ganja smoking was noted in 32 of the cases; opium smoking did not give a single case but opium eating accounted for two cases. With regard to the expenditure incurred, the average cost per head was Rs.11 less than in the previous year in Nagpore, and Rs.2 more per head than in 1905 in Jubbulpore. The report also shows, amongst other items, the religion, sex, and places of residence of the patients and their previous occupation. The age most affected was that between 20 and 40 years.

Rangoon.

A note on the Rangoon Lunatic Asylum for the year 1906 is furnished by Colonel W. G. King, I.M.S., the Inspector-General of Civil Hospitals of Burma. Here there was an increase of 27 inmates on the last day of the year 1906 as compared with that of 1905, there being 493 in 1906 as against 466 in 1905. The total accommodation provided at the small rate of 50 superficial feet per head suffices only for 429, so that there is considerable overcrowding which was confined to the criminal and female sections of the asylum. In the absence of increased and more suitable accommodation contemplated by the erection of a new asylum it was ultimately found necessary to arrange for the transfer of criminal lunatics to the disused jail at Minbu and the necessary structural arrangements were undertaken in the latter months of the year, so that it was hoped during 1907 to effect a relief to the present undesirable conditions by causing a transfer of at least 80 criminal lunatics. With regard to the overcrowding of female lunatics, a dilapidated building in the existing asylum has been sufficiently restored to permit of its use for 12 inmates. During the year an effort was made to ascertain whether it was possible to board harmless lunatics with private persons, under occasional medical supervision, and the results were favourable to this course. Much attention has been paid to the water-supply, where there were obviously possibilities of gross pollution owing to faulty methods of lifting. A "safety elevator" was purchased and worked efficiently. The trenches were removed farther from the possible drainage zone and two filters of six Berkefeld candles each, worked by pressure under hand-pumps, have been put in use during 11 months of the year. The result has been extremely satisfactory, the rate of admission for "bowel affections" in 1906 being 53·23 per 1000, as contrasted with that of 158·80 per 1000 in 1905.

Much forethought has been exercised over the details of the proposed new asylum, Lieutenant-Colonel G. J. H. Bell, I.M.S., having been deputed to visit India for the purpose of examining the different methods of administration and the structural details of the asylums there, so that any points of value might be available for the internal economy of the building. In the meantime the Department of Public Works is to modify certain wards in the existing asylum so as to arrive at a definite opinion as to various details connected with the comfort, supervision, and safe custody of severe cases of lunacy. With regard to the diet, which is entirely vegetable, Colonel King is trying to secure from China soybeans, the typical bean for the diet, for purposes of cultivation in the asylum. Respecting the death-rate, this was the lowest on record during the last ten years with the exception of that for the year 1900. The daily average of sick was 31·07 of the strength, against 31·69 of the previous year 1905. Malarial fevers only accounted for nine cases. Beri-beri gave one case which was imported, but there was naturally some anxiety as to the spread of this disease owing to the overcrowded state of the asylum. This fortunately did not, however, occur. Tuberculosis caused six deaths in 1906, an increase over 1905, in which year there were only two cases admitted. With reference to the various types of insanity admitted we find that mania headed the list, followed by melancholia, and then dementia.

Lastly, respecting the expenditure, this increased per head of average strength per annum from Rs.149 7a. 5p. in 1905 to Rs.158 8a. 3p. in 1906, whilst the total expenditure in 1906 was Rs.75,293, against Rs.67,855 in 1905. This increase was due to the fact that the full staff sanctioned by the Government of Burma in 1905 was entertained. It is, however, gratifying to note that there was a material saving of Rs.2 14a. 4p. per head under "contingencies," an item under which if supervision be not careful much extravagance may result. Had, in fact, the cost of the establishment been the same as during the preceding year, the total cost per head for 1906 would have been Rs.143 5a. 3p., against Rs.149 7a. 5p. in the preceding year. A net profit in 1906 under manufactures of Rs.14,165, as against Rs.1,21,836 in 1905, together with a decline of injuries from 6·39 per cent. of average strength in 1905 to 2·74 in 1906, certainly imply a better grade of supervision by this increased staff. This so-called "Note" is a model of what a report should be; all the facts are set forth in a concise, readable form, such as would be expected from an officer of Colonel King's well-deserved reputation.

BRITISH MEDICAL BENEVOLENT FUND.

AT the February meeting eight applications were received and grants amounting to £94 were voted in relief. The following is an abstract of the cases :—

Daughter, aged 53 years, of late L.F.P.S. Glasg. Only income £10 a year from a charity and is unable to make any effort at self-support owing to ill-health. Relieved once, £12. Voted £12 in 12 instalments.

Widow, aged 65 years, of M.D. Aberd. No income. Earns a little by sewing. Children unable to help. Relieved seven times, £90. Voted £12 in 12 instalments.

Daughter, aged 55 years, of late L.S.A. No income. Lets rooms, but finds difficulty in getting lodgers and has been obliged to sell most of her furniture. Voted £10 in ten instalments.

Widow, aged 46 years, of M.B. Durh., M.R.C.S. Eng. No income; endeavours to support herself by letting lodgings. Two children, aged 16 and 14 years. Voted £12 in 12 instalments.

Widow, aged 59 years, of L.R.C.P., L.R.C.S. Irel. Was provided for at husband's death, but lost everything through the failure of a bank a little more than a year ago. Slight help from a sister who earns a living as companion. Relieved once, £12. Voted £12 in 12 instalments.

Daughter, aged 62 years, of late M.R.C.S., L.S.A. Maintained herself for many years but is now deaf and in indifferent health and unable to get work. No income; a friend pays the rent of a room. Relieved nine times, £103. Voted £12 in 12 instalments.

Widow, aged 44 years, of M.D. R.U.I. Quite unprovided for at husband's sudden death some years ago and now acts as housekeeper, receiving a home for herself and only child in exchange for her services. Relieved nine times, £107. Voted £12 in 12 instalments.

Daughter, aged 65 years, of late M.D. Edin. Supported herself until nearly 60 years old, but for the last few years has had to live with an aged mother, an annuitant of this fund. Applicant has recently been operated upon for new growth. Relieved four times, £24. Voted £12 in 12 instalments.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY AND THE MIDWIVES QUESTION.

THE following is the report of the Midwives Committee of this society, which has received the unanimous approval of the council of the society :—

This committee was appointed for the purpose of considering the working of the Midwives Act, and reporting thereon, especially in reference to the remuneration of medical practitioners called in by midwives.

The committee accordingly directed that a circular letter should be addressed to members of the society, and other medical practitioners, and also published in the medical press, asking for (1) information as to the number of confinements to which each medical practitioner had been summoned by midwives under the regulations of the Midwives' Board; (2) what payment they had received in each case, and from whom; (3) and what was the nature of each case to which they were summoned.

Several hundred replies were received, and the following information has been derived from them :—

A large number of practitioners replied saying that they had never been summoned by midwives, several saying that there were no midwives in their districts.

In considerably more than half the cases the medical practitioners summoned by midwives received no payment whatever, and the average payment, calculated from a large number of cases, was not over 9s. A noteworthy point is that while some practitioners seem to be uniformly unpaid a few seem to be almost uniformly paid. Probably the class of people in the districts concerned accounts largely for this; but, in one or two instances, the explanation given by the medical practitioner was that he refused to go unless paid.

Of the fees received all but a few were received from the patients or their relatives, and it seems to be quite exceptional for payment to be made by the midwife. A few fees were paid by boards of guardians, nursing associations, provident dispensaries, &c.

The cases to which the medical practitioners were summoned were in the great majority serious ones. Operative assistance was required in many cases. The largest number of the less serious cases were described as delayed or difficult labour. In about 3 per cent. of the cases the death of the child appears to have been the cause of the summoning of the doctor, and puerperal fever was the cause in about 2 per cent. of the cases.

Grave dissatisfaction was expressed by many of the writers at the present state of affairs, and it is evident from the tone of many of the letters that unless proper provision is made for the payment of doctors capillaries. Such transudation takes place most commonly in the skin, setting up urticaria, and frequently also in the bronchial mucous membrane, producing the symptoms of asthma. It is in this way that an attack of urticaria is caused by the eating of shell-fish. In countries where eggs are a common article of diet tolerance to the action of the decalcifying substance derived from them is almost universally present. The boy whose case is recorded by Dr. Schofield seems never to have acquired this tolerance. Such tolerance as regards shell-fish, a diet much less general in its use, is, as we know, often wanting. To express the theory in the terms of present-day pathology, the decalcifying substance produces in the blood an anti body and then tolerance is established. Dr. Schofield, who is to be congratulated on the result of his treatment, fully succeeded in developing the anti-body in his patient's blood and the liability to poisoning was overcome. Similar treatment would be worth practising in the cases of intolerance to various foods—e.g., mutton—which are occasionally met with. It would be interesting to learn whether the yelk of egg had a poisonous effect or whether this was confined to the white.

I am, Sir, yours faithfully,
Wimpole-street, W., March 7th, 1908. R. HINGSTON FOX.

DELAYED CHLOROFORM POISONING.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 29th an article appeared from Mr. E. D. Telford reporting three cases of what he describes as the above condition. He informs us in his last paragraph that we are no nearer to a solution of these mysterious cases and that it is essential that all cases should be fully reported. Now, what is the example that he sets us? He is so anxious to tell us how nicely his operation wounds healed that he has quite forgotten to say what method was employed by the anæsthetist. He also tells us nothing about any symptoms that appeared during the anæsthesia, or whether the anæsthetic was administered by an expert, or by someone who did not fully appreciate what he was doing or should do in any circumstances that might arise during the administration. He further omits to mention how the patient was prepared in two of the three cases or how they were treated immediately after the operation. Mr. Telford states that the changes found post mortem are probably due to the anæsthetic, but this I think is very questionable on account of the enormous amount of degeneration sometimes found, especially in the liver, within two days of an administration of a drachm or so of chloroform. Why, for instance, should it not equally be due to the castor oil or the enema?

I have never yet seen a case of this kind, and other anæsthetists seem to be in the same position; while the surgeon seldom knows whether chloroform, or a mixture containing chloroform, has been employed; neither does he know whether oxygen has been administered in conjunction with the anæsthetic. Until the anæsthetists are given an opportunity of going into the cases *before the death of the patient*, we are not likely to arrive at the true cause and preventive treatment of the condition. Most of the patients apparently suffer from rickets, but so do thousands of others who exhibit no such symptoms. The resident medical officer of the same hospital reports two similar cases on the authority of the surgeon. He tells us that chloroform was used in each case, but he likewise omits to mention the method or any symptoms that occurred during the administration. Since these occurrences are so frequent at this one particular hospital it is most important that more of the details of the anæsthesia with less about the operation, should be published.

Another case is reported by Dr. H. C. Wilson, also on the authority of the surgeon, and without obtaining any notes from the anæsthetist. He gives an excellent account of the condition, but apart from stating that one and a half ounces of chloroform were administered during one and a half hours, he tells us absolutely nothing about the very feature which it is attempted to prove is the cause of the whole condition. The remaining case is published by Dr. H. Thorp who certainly tells us a little more than the others, for he says: "The anæsthetic was well taken," in addition to mentioning that two drachms of chloroform were administered during seven minutes.

Such notes as these will never help to prevent the fatalities occurring. Some at least of the patients should have been given the C.E. mixture rather than chloroform; but if the anæsthetist were consulted he would probably inform us that this was in fact done. As a preliminary I should like to know (1) what kind of chloroform was employed; (2) who was the maker; (3) if ether was added, what kind of ether and in what proportion; and (4) how exactly did the patient behave throughout the various stages of the administration, and what degree of anæsthesia was maintained.

I am, Sir, yours faithfully,
London, W., March 4th, 1908. ROWLAND W. COLLUM.

OPEN WINDOWS AND ADENOIDS.

To the Editor of THE LANCET.

SIR,—Adenoid growths in the naso-pharynx of children are likely in the near future to assume a greater degree of importance on account of the medical inspection of schools under the now famous Section 13 of the Act of last year. Already an increasing number of children arrive at the hospitals, their parents having been recommended to get their throats treated. The best way to settle a question such as that raised by Dr. J. Sim Wallace would be by means of school children, vast numbers of whom are accessible. Dr. Wallace's figures are altogether too small to serve as a foundation for any generalisation bearing upon adenoids, which is very far at present from being a simple subject. It would no doubt be desirable, and would certainly be interesting, to make a comparison between the prevalence of adenoids now and 30 years ago. But it seems to me as hopeless a task as it would be to compare, e.g., appendicitis now and 30 years ago. Histories of cases will no doubt help, but they are equally certain to mislead.

As regards deformities of jaws and teeth we are not all agreed on the exact relation between them and adenoids or other form of nasal obstruction. According to my observation such deformities are very rare in the younger children who apply for treatment, but occur with increasing frequency in the later years of childhood when the second dentition is well advanced. These latter are presumably neglected cases. If these deformities stand to adenoids in the relation of effect and cause it follows that radical treatment of adenoids at an earlier stage ought to reduce the frequency of the deformities. Statistics showing a gradual diminution of dental and palatal irregularities with other statistics showing simultaneous increase of radical treatment of adenoids would prove the causal relation in a satisfactory manner. But the ground covered must be very wide to be convincing. Some such work appears to me essential before palatal or dental deformities can be accepted as proof of past adenoids in persons of 30 or 40 years of age.

I cannot believe that open windows have anything to do with adenoids unless it be in the way of preventing them. My experience of the poorer quarters of London is limited to six weeks' midwifery practice as a student in St. Luke's, Clerkenwell, and Islington. The open window was then (six years ago) a phenomenon sufficiently rare to attract attention. Those districts grew, and still grow, large quantities of adenoids. It is stated in books by responsible authors that adenoids are exceedingly rare among savages and other uncivilised persons who have no windows to open and of whom many are exposed to climatic influences quite as unfavourable as we in England. On the other hand, I have never seen such a collection of "typical adenoid faces" as in a crowd of children which I observed (August, 1907) in a south-western coast town justly famed for the mildness and salubrity of its climate. However, an absolutely certain diagnosis of adenoids can only be made by the eye or the finger.

I am, Sir, yours faithfully,
T. JEFFERSON FAULDER.

Welbeck-street, W., March 2nd, 1908.

THE STREAM HILL SANATORIUM SITE.

To the Editor of THE LANCET.

SIR,—My attention has been directed to the anonymous letter in your issue of Feb. 22nd *re* the site which I have given to the County of Cork Joint Hospital Board to erect a sanatorium on. As some of your medical contributors may be wasting time giving "Valetudinarian" unnecessary information, it is as well for me to state at once that no bulrushes grow on the ground, the earth surface is not peat mould, and that the under stratum is not yellow clay. The site has been closely inspected by a medical and an engineering inspector result precluded the suggestion that there had been a mistake, and the defendants, Messrs. T. Richards and Co., Limited, of Fetter-lane, were fined £8 with 18*s.* 6*d.* costs.

A Case of Cocaine Poisoning.

At the Central Criminal Court on March 5th, before Mr. Justice Bucknill, Isidor Zeifert, a dentist, whose name is not on the Dental Register, was indicted for and charged on the coroner's inquisition with the manslaughter of a patient who had died under the administration of cocaine. The defendant, who gave evidence in his own defence, said that he had studied medicine in Russia and had taken the primary degree of Bachelor of Medicine, but before passing his final examination he became involved in political matters and had to leave his country. He came to England and acted as assistant to medical men and dentists in London. He had been for 13 years in constant practice as a dentist and this was the first time he had ever had an accident. He had administered cocaine to his patients many times, and this was the first occasion any ill consequence had followed. The defendant's counsel, in his address to the jury, denied that there had been any negligence. Mr. Justice Bucknill, in summing up, said that the defendant was charged with the manslaughter of the woman who was his patient. In this connexion, guilt meant that he caused the death of the woman by wicked and culpable negligence in the reckless administration of a drug in such circumstances that he must have known that he was doing something that was dangerous, and yet did it recklessly and brought himself within the pale of the criminal law. If the jury could not find that, or if they had any doubt about it, they must find him not guilty. The learned judge referred to the fact that cocaine was extensively used by dentists, and very often without an examination being made as to the state of the patient's health. He also alluded to the difference of medical opinion as to what would be an excessive dose and to the fact that cocaine was a most uncertain drug, it being impossible to say what its effects would be on any particular person. The jury found the defendant "Not guilty," when Mr. Justice Bucknill, in discharging the defendant, said: The jury have found you "Not guilty," and I agree entirely with that verdict. Let me remind you, so that you may be wiser in the future—take my advice, that with the knowledge that we now have of cocaine, and that you have, it will be extremely unwise of you if you ever administer it without first ascertaining the condition of the patient's heart.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8820 births and 5493 deaths were registered during the week ending March 7th. The mean annual rate of mortality in these towns, which had been equal to 18·6, 18·4, and 17·3 per 1000 in the three preceding weeks, rose again to 17·6 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these towns averaged 18·3 per 1000; the mean rate in London during the same period did not exceed 17·9. The lowest annual death-rates in the 76 towns last week were 7·9 in Leyton, 8·0 in East Ham, 8·4 in Barrow-in-Furness, and 9·5 in Walthamstow; in the other towns the rates ranged upwards to 24·3 in Rhondda, 26·1 in Swansea and in Hanley, and 28·4 in Stockton-on-Tees. The rate of mortality in London last week did not exceed 17·2 per 1000. The 5493 deaths in the 76 towns last week showed an increase of 119 upon the low number in the previous week, and included 414 which were referred to the principal epidemic diseases, against 335 and 374 in the two preceding weeks; of these, 149 resulted from whooping-cough, 109 from measles, 65 from diphtheria, 48 from diarrhœa, 23 from scarlet fever, and 19 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·3 per 1000, the rate from the same diseases in London being 1·2. No death from any of these epidemic diseases was registered last week in Wolverhampton, Blackburn, St. Helens, Coventry, Hornsey, or in seven other smaller towns; the annual death-rates from these diseases ranged upwards, however, in the other towns to 3·1 in Rhondda, 3·7 in Salford, 3·8 in Reading, and 5·9 in Stockton-on-Tees. The fatal cases of whooping-cough in the 76 towns, which had been 170 and 138 in the two preceding weeks, rose again to 149 in the week under notice; the highest death-rates from this disease last week were 1·5 in Handsworth and in Smethwick, 1·6 in Wallsall, 2·0 in Sunderland, and 2·2 in Northampton. The 109 deaths from measles showed a further increase upon the numbers in recent weeks, and caused the highest death-rates, 1·6 in Rhondds, 1·8 in York, 2·3 in Croydon, and 3·9 in Stockton-on-Tees. The deaths referred to diphtheria, which had been 52 and 47 in the two previous weeks, increased to 66 last week, the highest proportional mortality from this disease being equal to rates of 1·2 in York and 1·5 in Salford and in West Bromwich. The 23 fatal cases of scarlet fever were fewer than in any previous week of this year, but included ten in London, two in Liverpool, and two in Oldham. The 48 deaths attributed to diarrhœa showed a further slight increase. Of the 19 deaths referred to "fever," fewer by five than those in the previous week, two each were returned in London, Bradford, Middlesbrough, and in Sunderland. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the 13 preceding weeks from 5581 to 3674, had further fallen to 3567 on March 7th; 345 new cases were admitted to these hospitals during last week, against 473, 420, and 383 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 451, 427, and 384 in the three previous weeks, further declined to 325 in the week under notice, and were 34 below the corrected average number in the corresponding week of the five years 1903–07. The deaths in London attributed directly to influenza last week were 122, against numbers increasing steadily from 32 to 141 in the five preceding weeks. The causes of 56, or 1·0 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified last week in Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 48 other smaller towns 15 uncertified causes of deaths were, however, registered in Liverpool, nine in Birmingham, six in Sheffield, three in Sunderland, and two both in Gateshead and in South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21·8 and 19·2 per 1000 in the two preceding weeks, was 19·3 in the week ending March 7th, and exceeded by 1·7 the mean rate during the same week in the 76 large English towns. Among the eight Scotch towns the death-rates ranged from 15·9 in Edinburgh and 16·7 in Greenock to 20·7 in Perth and 22·0 in Dundee. The 681 deaths in these eight towns exceeded the number in the previous week by four, and included 96 which were referred to the principal epidemic diseases, against 92 and 99 in the two preceding weeks; of these, 47 resulted from measles, 18 from whooping-cough, 11 from "fever," seven from scarlet fever, seven from diarrhœa, and six from diphtheria, but not one from small-pox. These 96 deaths were equal to an annual rate of 2·7 per 1000, which exceeded by no less than 1·4 the mean rate from the same diseases last week in the 76 English towns. The fatal cases of measles, which had been 35 and 41 in the two preceding weeks, further rose to 47 in the week under notice, and included 31 in Glasgow, five in Edinburgh and in Aberdeen, three in Paisley, and two in Greenock. The 18 deaths from whooping-cough corresponded with the number in the previous week; nine were returned in Glasgow, three in Dundee, three in Leith, and two in Edinburgh. Of the 11 deaths referred to "fever" in the eight towns, showing a further slight decline from the numbers returned in recent weeks, eight were certified as cerebro-spinal meningitis and three as enteric; six occurred in Glasgow and two both in Paisley and in Leith. The seven fatal cases of scarlet fever showed a slight increase, and included three in Glasgow and two both in Edinburgh and in Aberdeen. The seven deaths attributed to diarrhœa showed a considerable decrease. Of the six deaths referred to diphtheria, fewer than in any recent week, three occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 184 and 137 in the two preceding weeks, rose again to 155 in the week under notice, and were six below the number returned in the corresponding week of last year. The causes of 21, or 3·1 per cent., of the deaths in these eight towns last week were the hospital-man, and then cut me down to a paltry pittance. I suffer in the long run. *To do this the* hospital man gives away, each of them at more than one so-called charity, my daily resources, the nimble half-crown, in the out-patient departments, in order to be able to 'do a scoop' on occasion when my richer patients have need of him, and then sneak my patient and *his friends afterwards* because I am not as practised in skill as he is. When I can, I send my patients who are neither *poor nor rich into hospital* and compel the hospital-man to give away *his own* living by way of a change and see how he likes it. *Do you* think I am going to let him come and clean out a poor devil who owes me an account as it is and then *get left myself?* No, Sir, *into hospital he goes*; the fellow who sells me to make his position operates on him for nothing, out comes my patient, pays me what he owes me, and gets a little *holiday at the seaside into the* bargain. *Two can play at the* same game with advantage."

The above is positively what is steadily taking place, and is actually being brought about by the methods *of* the hospital practitioners themselves. The tables are *being turned* with a vengeance, hence the cry which has lately *sprung* up amongst hospital practitioners that *there is hospital abuse*, a fact they steadily denied whilst it harmed only that "*poor fool*" the trusting and long-suffering general practitioner amongst the lower *middle* classes.

Dr. Saundby's letter contained at the end some sentences which I would like to deal with. He says: "As it [my proposal] is *dangerous* to the public as well as to the profession and *offers* such serious temptations it should be nipped in the bud. It may be advocated as justice to the general practitioner but it means dishonour to the *profession.*" It seems a thousand pities that Dr. Saundby's paucity of resource should drive him to draw upon unworthiness of his profession. It would have *been* bad enough if it came from a spiteful general practitioner speaking of "specialists," but coming from a consultant and a former *President* of the British Medical *Association* and chairman of its ethical committee, a *member* (I believe) of the General Medical Council, and an author of a work on "Ethics," its gravity is overwhelming! It is the hardest thing that can be said against any body of men. Dr. Saundby surely forgets that the profession which to-day asks for the trust of the public must of necessity be the same men who, Dr. Saundby asserts, will succumb to "serious temptations" and so court "dishonour." If they prove untrustworthy, then they cannot be trustworthy now if he is to be believed. He cannot have it both ways.

What code of "ethics" outside Bedlam is it that justifies the perpetuation of injustice to the general practitioner for fear of dishonour to the whole profession? How can anything that can be "advocated as justice" to a section of a community bring dishonour to the entire community? *How can justice mean dishonour?* Is it then the fact that the general practitioner's anomalous fiscal position constitutes the only check on the would-be dishonesty of the "specialist" and so averts "danger to the public" and danger and "dishonour to the profession"? Is it meant that both general practitioners and hospital practitioners will go into collusion—in plain English, conspire to rob the public—because the general practitioner gets "justice"? Does Dr. Saundby desire us to accept it as certain that if the medical profession be placed in a position of trust they will succumb to a man and become so easily dishonoured? Are they not for the most part subject now to "serious temptation"? And are they all *dishonourable*? He speaks of "danger to the public"; surely this must mean something more than mere *fees*? *Does "dishonour"* not tend to accrue when, in any community, a section is adversely treated in favour of another *section*? Does he mean that only the general practitioners are keeping the profession from dishonour and that if their position were improved and put on all fours with that of the hospital practitioners the *latter's* unchecked methods would mean general "dishonour" because it would have a free rein by reason of the general *practitioner's* interests being identical? Dr. Saundby need not fear for the physician's odd two or three *guineas for* a consultation. Only let him and others remember that a fee, in proportion, is due to the general practitioner *for "meeting* the physician" in consultation.

Does Dr. Saundby think that general practitioners *do* now, and will in *future*, call in "physicians" for the sake of an extra fee? Does he expect your readers to believe him? He surely places a *very contemptuous value on the* services of the general practitioner in *his letter*. Which of any two men will be the *more likely to keep* and maintain the honour of the profession—one who *modifies* his fees to meet *his patient's means* and helps and *supports* his brother medical man, or the man who selfishly grasps all he can lay *hands on, leaving* the general practitioner to eke out a *living* as best he can whilst using the sources of that general practitioner's *daily* bread as a lever in hospital work to get into a position to be able to ignore the general practitioner's *claims* to be fairly dealt by?

It would be far better if we flung such rotten "ethics" to *the four* winds of heaven and went in for wholesale and universal throat-cutting, pure and simple. One would then know what to expect and not be caught napping. Expect nothing except that which one appropriated unasked and therefore suffer no disappointment and resentment for unfair treatment. What can be said for the "honour" of a profession in which one class lives by preying on the resources of the other class, arrogates to itself the better position, makes the laws to be observed in its *own* selfish interests, parcels out all the chances in life amongst its units, closes its ranks to entry from the other class and to *do so* breaks unchallenged every law of God and man—"Live and let live"? Lest it be thought that I exaggerate, I will relate what many of your readers will learn with some astonishment. A few days ago an appointment was made to a dispensary for out-patients only, in London, involving two afternoons' work per week; seeing minor surgical cases, whitlows, cut fingers, rheumatic joints, boils, abscesses, &c. There was attached to this paltry appointment a stipend of 50 guineas per annum (miscalled an honorarium) for doing charity! This appointment would suit, and ought only to be held by, a very youthful and inexperienced "specialist," or a general practitioner whose ambition lay in worthy and honourable lines. There applied, amongst others, for this post and got it, a full surgeon on a large teaching and a non-teaching hospital, in both of which places he "had beds." Now, Sir, is this not subversive of fair play as between seniors and juniors? I was not a candidate for the above post.

I have been saying unpleasant things and ask a little more space for a most pleasing contrast. I inclose you the appointment card sent by a *consultant* to a general practitioner's patient making an appointment, and which was handed to me by the general practitioner himself. We both spent much time saying many good things about that "*consultant.*" I wish that I could publish his name. On the back of this card is printed the following:—

> Dr. —— does not undertake the *continued treatment of patients* or visit them in their own homes except in *coöperation* with their usual medical attendant, and whenever possible a note of previous health should be brought from him.

This notice incidentally makes an excellent definition of a "consultant," and *no man* who does not conform to the above has any right to demand "consultant fees." Will Dr. Saundby please take *note of* the above and put it to the credit of a profession that must "deny justice" lest "dishonour" follow in its train.

I am, Sir, yours faithfully,
F. W. FORBES-ROSS, M.D. Edin., F.R.C.S. Eng.

London, March 6th, 1908.

"THE CASE FOR THE GOAT."

To the Editor of THE LANCET.

SIR,—I am *greatly obliged to* you for having, in your kind review of my little book, "The Case for the Goat," drawn my attention to a clerical slip in the table on p. 11 which I shall correct at the earliest opportunity. It should *read as follows*:—

—	*Goat's milk.*	*Cow's milk.*
Water	83·21	87·56
Butter-fat	7·30	3·63
Casein	4·18	8·81
Milk sugar	4·10	
Ash...	1·21	

In my book the table appears—I cannot tell now whether the omission is due to typist, *printer, or* author—minus the

Correspondence.

"Audi alteram partem."

THE PARATHYROID GLANDS.

To the Editor of THE LANCET.

SIR,—In an interesting paper on the parathyroid glands recently reviewed by you[1] Dr. David Forsyth expresses the opinion that these bodies have no peculiar function and that their secretion is identical with that of the thyroid gland. These conclusions are based on the careful examination of a large number of thyroids both from man and the lower animals and on general considerations, but not on experiments on living animals, for Dr. Forsyth holds that any attempt to remove the parathyroids at the same time leaving the thyroid proper will be either incomplete, or if complete, accompanied by so much injury to the thyroid as to make any inferences untrustworthy. This view is also taken by Dr. Swale Vincent and Dr. W. A. Jolly[2] who consider that "when parathyroidectomy proves fatal this is probably due to the severe damage simultaneously done to the thyroid"; but Dr. Vincent and Dr. Jolly themselves relate[3] an experiment on a cat in which both thyroid lobes and three parathyroids were removed, leaving only one parathyroid; the cat remained well; 13 days later the remaining parathyroid was removed, the cat died 17 days after this with "typical symptoms." The fact that the cat died after the second operation shows that it was not one of those animals which are not affected by complete excision and that it survived the first operation shows that the disturbance then inflicted on the parathyroid left was not sufficient to destroy it functionally; apparently the cat's life was first saved by leaving the parathyroid and later destroyed by removing it. I have recently had a similar experience; from a dog there was excised on the right side the thyroid lobe leaving only one parathyroid with possibly a minute portion of thyroid proper; the dog remained well. 61 days later the left lobe with its parathyroids was removed. The dog still remained well. 113 days later the remaining parathyroid was excised. In ten days the dog died with the usual acute symptoms.

But the case for the parathyroids does not rest only on microscopic appearances and experiments on animals. The thyroid contains a considerable amount of iodine, while according to Estes and Cecil iodine, if present at all in the parathyroids, only occurs in such minute quantities as to be of no functional significance.[4] Easterbrook found that while thyroid extract was a powerful metabolic stimulant parathyroid extract produced little or no effect in the patients to whom he gave it.[5] Hutchison found that parathyroid feeding had no effect in myxœdema,[6] and others state that it has no effect in Graves's disease, in which thyroid extract and iodides are said to do harm.[7] It must not be inferred that interference with the parathyroids produces no ill effects. The affection known as operative tetany is thought to be due to this; out of 52 extirpations of the thyroid in Billroth's clinic tetany occurred in 12 cases and proved fatal in nine. Dr. W. S. Halsted has recently recorded an interesting case of the disease from a woman with a large and rapidly growing goitre. One lobe was excised. Care was taken not to include any parathyroid and on examination of the part removed none was found. The case did well but the remaining lobe increased in size and two years later was excised; on this occasion, notwithstanding due care, a parathyroid was found in the part removed; the patient did not make as good a recovery as before, but was subject to serious "attacks" with a sense of numbness. During these attacks the patient felt and appeared to be very ill. Dr. Halsted felt so confident of the nature of these attacks that he at once commenced parathyroid feeding: "the effect of parathyroid exhibition was almost instantaneous and most marvellous."[8]

Again, it is possible that the parathyroids may have to do with the good effect in Graves's disease claimed for the milk from thyroidless goats.[9] The excision of the thyroid with its accompanying parathyroids does not produce at the time any obvious effect in sheep and goats; but Horsley[10] has recorded a case in a sheep in which myxœdema came on 20 months after operation, and I have seen two cases in goats in which the operation was followed by myxœdema, temporarily benefited by thyroid feeding,[11] but the symptoms in these cases were very different to the severe nervous symptoms, tremors, paralysis, convulsions, and death, which in a few days follow the complete extirpation in dogs and cats. The explanation of this appears to be now forthcoming. Recently, Dr. MacCallum, Dr. Thomson, and Dr. Murphy[12] have found that there exist in the goat four parathyroids, two in the thyroid, and two in the thymus. Further, they found in two out of several experiments that if the thymic parathyroids were excised together with the thyroid and its parathyroids severe symptoms came on which proved fatal in a few days; the good effects produced by the milk of thyroidless goats is usually attributed to its containing some substance antagonistic to the thyroid, this substance neutralising the excessive secretion of the enlarged thyroid of Graves's disease; it suggests itself that this substance may be derived directly or indirectly from the thymic parathyroids left in the thyroidectomised goats.

It is true of all the experiments cited that the results do not uniformly follow in a series of operations, but the view that the thyroid and parathyroids are functionally identical does not relieve us from this difficulty, for in dogs the complete operation is followed by early death in about 95 per cent. of the cases, the remaining 5 per cent. recovering without ill-effect. One of the problems connected with Graves's disease is whether it is to be regarded as starting in the central nervous system or in the thyroid gland; some of the cases have a history of nervous strain, others of acute infectious disease; in others, again, the disease is preceded by an ordinary goitre without symptoms. These various origins seem to be brought into line by the experiments of Tedeschi.[13] He confirmed Filehne's observation that the symptoms of Graves's disease can be produced by an injury to the restiform bodies and he further found that the symptoms could be prevented by excision of the thyroid before the restiform operation, and that when caused by that operation they could be diminished by a subsequent excision of the thyroid. If a central nervous lesion can cause the peculiar change in the thyroid its secretion could cause the other symptoms; with respect to infective diseases it is easy to see that their toxins might affect the nerve centre. Lastly, in cases of apparent thyroid origin no doubt the centre and the gland would early act and react on one another.

I am, Sir, yours faithfully,

Devonshire-place, W., March 7th, 1908. WALTER EDMUNDS.

THE BLOOD CONDITION IN EGG POISONING.

To the Editor of THE LANCET.

SIR,—Referring to Dr. A. T. Schofield's interesting case of egg poisoning reported in your last issue I should like to inquire whether the coagulation time of the blood was ascertained, and if so whether the time had diminished after tolerance to egg diet had been established. Following the teaching of Wright, I suggest a different theory of the poisoning from that put forward by Dr. Schofield. Eggs, like shell-fish, contain a powerful decalcifying substance, supposed to reside chiefly in the membrane which incloses the albuminous material of the egg. On the outer surface of this membrane the shell is formed, consisting principally of calcium salts, the substance in question having the power of selecting the calcium dissolved in surrounding media and precipitating it in a solid form. When the decalcifying substance is taken into the human stomach it finds its way quickly into the blood, and in individuals who are not tolerant of its action reduces the fibrin-forming power of the blood by precipitating the calcium salts on which that power depends. Hence there is diminished coagulability, and transudation of lymph through the walls of the kept waiting for months before they can be admitted, will be rectified. The balance on the hospital erection fund stands at £37,809 and the cot endowment fund at £4345.

The late Mr. E. R. Bickersteth.

The death occurred on March 7th of Mr. Edward Robert Bickersteth, F.R.C.S. Eng., consulting surgeon to the Liverpool Royal Infirmary, in his eightieth year. Mr. Bickersteth had been in bad health for several months. It is a strange coincidence that Mr. Bickersteth should only have survived his former colleague the late Mr. Reginald Harrison one week.

March 10th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Appointments at the University.

CONSEQUENT on the resignation of the late Professor C. J. Wright the council of the University has appointed Dr. John B. Hellier as professor of obstetrics. Dr. Hellier has been connected for many years with the school of medicine and with clinical teaching in Leeds. Himself a student of Leeds, he was at one time teacher of materia medica and more recently has been lecturer on gynæcology. His promotion to a professorship will add to the Senate of the University a man of sound judgment, and his position as honorary obstetric physician to the infirmary will enable him to correlate the instruction to the students which comes on the one hand from lectures and on the other from practical work. Dr. E. O. Croft, who was formerly honorary demonstrator of midwifery, has been appointed to succeed Professor Hellier as lecturer on gynæcology. Dr. R. Veitch Clark, who was formerly demonstrator of physiology and who was recently appointed assistant medical officer of health of the city, has been appointed by the council honorary demonstrator of public health under Professor J. Spottiswoode Cameron.

The Workpeople's Hospital Fund.

The twenty-first annual meeting of the supporters of the Leeds Workpeople's Hospital Fund was held on Feb. 26th under the chairmanship of Mr. F. R. Spark who initiated the movement and has been not only the honorary secretary and for many years the chairman of the fund but has been the life and soul of the endeavour throughout. At one time the voluntary subscriptions of the workpeople at the various factories and workshops of Leeds were paid directly to the different charities which it was desired to benefit. It was then agreed that the collectors of the infirmary and of the other institutions should cease to collect such subscriptions within the city boundaries and that a specially organised fund should be started. The movement has from the beginning been attended with every success. It is true that the money collected does not now go, as it did at first, entirely to the charities, and that the committee has deemed it wise and within the scope of the movement to make extensive capital outlay in the provision of convalescent homes, the maintenance of which, of course, involves an annual demand on the amount collected and that these homes are reserved exclusively for the use of subscribers to the fund. Though in this respect the fund cannot be strictly regarded as one devoted entirely to charitable purposes, it is satisfactory to note that the amounts voted to the different institutions have not lessened since this new policy was entered upon but have increased considerably. The main source of income is derived from the voluntary subscription on the part of the workers of a weekly sum of 1*d.* in the case of men and of ½*d.* in the case of women, girls, and boys. In many cases the workpeople have authorised their employers to keep back this amount from their wage, an arrangement which facilitates the collecting of the money, and is being increasingly fallen in with. From this source the amount collected during 1907 was £9781, as against £9137 for 1906. Other sources of income are collections made at public-houses, matinées, football matches, Sunday concerts, carnivals, and various collections, in addition to the annual gala, the success of which depends mainly on that uncertain factor, the weather. With a balance brought forward from last year of £1730, and with the addition of a special donation of £1000 the total receipts for 1907 amounted to £15,983. At the annual meeting the Lord Mayor made a donation of 21 guineas, so that the handsome sum of £16,000 was realised. From this grants were made as follows: Leeds General Infirmary, £5250; Leeds Public Dispensary, £800; Hospital for Women and Children, £800; Tuberculosis Association, £315; District Nursing Association, £250; Maternity Hospital, £125; Bramley District Nursing Association, £50; and Stanningley District Nursing Association, £50. During the year the Convalescent Home for Men at Horsforth has been enlarged and was reopened by Sir James Kitson (now Lord Airedale) on July 13th. Since the reopening 321 patients have been admitted. The regular time during which patients remain in is two weeks, but 115 of those admitted were on this occasion allowed to stay in three weeks. During the time when the home was closed for repairs 359 men were sent at the expense of the fund to other convalescent homes. The Convalescent Home for Women is at Ilkley, in Wharfedale, and to this 416 patients were admitted during the year. The total expenditure on both homes and on the general fund has been £7683, which includes £4319 of capital expenditure on the rebuilding of the Horsforth Home. The amounts voted to the different charities were the same as last year, and it is hoped that as the capital expenditure next year may be less there may be a proportional increase in the amount available for distribution.

March 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The University of St. Andrews and the late Professor J. Bell Pettigrew.

AT the Court of the University of St. Andrews which met last week a motion was unanimously adopted expressing great regret at the death of Dr. James Bell Pettigrew who for 33 years had been Chandos professor of medicine and anatomy in the University. It was also resolved to express to Mrs. Bell Pettigrew the heartiest thanks of the Court for the generous and munificent gift of £6000 which she is bestowing on the University in memory of her husband, and to assure her that the Court will be able through the gift to erect a commodious and well-arranged museum which it will associate with the name of Professor Bell Pettigrew. It was explained that by an ordinance of the University Court passed in 1900 it had been provided that the Chandos professorship of medicine, which the University Commissioners had enacted should come to an end at the termination of Professor Bell Pettigrew's tenure of the chair, should be continued after his death as a professorship of physiology. The business and finance committee will draw up a statement of the terms and conditions of appointment of a professor to the new chair.

Aberdeen Town Council and Street Accidents.

The watching committee of the town council of Aberdeen recommends that in cases of accident or of sudden illness happening in the street the police constable on whose beat it occurs should be authorised to send for the nearest available medical practitioner and that the fee of 2*s.* 6*d.* for day calls and 5*s.* for calls between the hours of 10 P.M. and 8 A.M. should be paid to such practitioner by the council.

Deer District Public Health Committee.

At a meeting of the above held in Maud on Saturday, Feb. 29th, circulars from the Local Government Board with regard to the Vaccination (Scotland) Act, 1907, the Notification of Births Acts, 1907, and the Public Health (Scotland) Amendment Act, 1901, were considered. It was agreed not to adopt the Vaccination Act or the Notification of Births Acts. The circular with regard to the Public Health Act was left to the sanitary authorities. The question of what constituted a dairy was under discussion, as, for instance, ought crofters to be registered as such who sold small quantities of milk to people with carts who went round and collected such small supplies.

March 10th.

BRISTOL MEDICAL MISSION.—The annual meeting of the subscribers to the Bristol Medical Mission was held on Feb. 25th. The medical report stated that 9050 patients were treated during 1907, including 1934 who were visited at their homes. The financial statement showed a small favourable balance.

of the Local Government Board and approved of. Nor was any evidence of medical value given against it at the recent inquiry, the only medical witness against it having not thought it worth his while to visit the site before giving his evidence. I am, Sir, yours faithfully,

LANGLEY BRASIER-CREAGH.

Stream Hill, Doneraile, Co. Cork, March 3rd, 1908.

THE HALL-EDWARDS FUND.

To the Editor of THE LANCET.

SIR,—Mr. J. Hall-Edwards, who is well known as a pioneer in this country in radiographic work, has as a result of this work developed cancer of the skin of both hands. It has been found necessary to amputate one hand and it is feared that he will lose the other. Mr. Hall-Edwards is in consequence deprived of the means of earning a livelihood, and has to face an uncertain future with the added distress of financial difficulty. It is hoped to raise a fund to put him beyond the reach of want, and for this purpose a local committee was formed at a meeting presided over by Sir Oliver Lodge on March 5th. About £600 have been promised, and it is hoped that the medical profession throughout the country will show its sympathy by contributing to the needs of one who by his pioneer work has helped to make the road easy and safe for those who follow him.

We are, Sir, yours faithfully,

ROBERT M. SIMON, M.D. Cantab., } Secretaries.
J. O. VAUDREY, }

41, Newhall-street, Birmingham, March 10th, 1908.

THE PRESENT PROSPECTS OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 29th you print a letter from Dr. Robert Saundby, intended, no doubt, as a reply to my letter in your issue of Feb. 22nd. With reference to Dr. Saundby's remarks concerning French medico-political history I beg to remark that I addressed myself to persons of the United Kingdom. I do not consider Dr. Saundby's remarks on the above score call for any comment from me. Persons who essay forth to "nip buds" must be careful lest inadvertence leads to thorny experiences.

Care on Dr. Saundby's part would have prevented his misrepresenting me, though his words in any case bear a peculiar importance and gravity which cannot be avoided. I spoke of "the fee agreed upon for the operation," one-third part of which should be apportioned "on the nail" to the general practitioner for his assistance at the operation and the major part of the after-attendance. As it takes two persons to make a bargain, I presume that the person paying the fee—the patient or the patient's friends—must needs agree to the fee paid. I positively deny that this is "dichotomy." It is nothing of the sort, it is a computed compound payment to two men for doing two men's work honestly. My proposal will insure the ultimate payment of the general practitioner if the so-called "specialist" is paid, and if not then the "specialist" is in "the same boat." Nowadays, with present methods, the "specialist" is often the only man paid, and the general practitioner has to whistle for his fees. My plan will also tend to keep many out of the hospitals, which apparently the hospital practitioners cannot or do not care to insure. Modern medical and surgical methods, instead of tending to cheapen treatment, as they ought to do, actually are made to render it more expensive and prohibitive to the sufferer of slender purse. The result is that more frequent resort is had to the hospital and so puts an increasing stress on charitable funds, whilst depriving a large section of the medical profession of an honest livelihood, and at the same time preserving to the public a self-respecting independence. Actually the methods of working, as between the profession and the public, is forcing hospital abuse "willy-nilly" on the public and turning the entire charitable system into a universal curse instead of a blessing. The public are and have long been desirous of a scale of charges as between themselves and the profession which will be final and inclusive. Instead of that our methods have been elaborated, till a serious illness, needing operation, is more disastrous financially than an earthquake or a fire. Why have the public not been met in this matter? Simply because it did not suit the pockets of the so-called "specialists" (hospital practitioners) who make and impose the rules which are known as "ethics." Those who suffer most are the public and general practitioner. The reason for this is that in any case the hospital practitioner gets material for "increasing his knowledge and perfecting his skill" which he could not otherwise obtain in such peculiarly favourable circumstances. He also derives a competitive advertisement from the better-class patients of his less fortunate "professional brother" (?), and finally is thereby enabled to set up a high financial standard of reward for his paid work, limit competition (financial and skilful), and keep a close corporation against the general practitioner, whose source of daily bread he helps to distribute gratis in hospital, in order to attain to the exclusive professional position he has usurped. When a "specialist" is wanted, under present ethical rules, he comes in, recommends certain procedures, which he carries out to his own sole financial profit at a high price, and departs. Apparently the "honour" of the profession, to judge from Dr. Saundby's letter, rests solely and simply on the predicament of the non-participating general practitioner. Clearly the "specialist" has no more to gain as he, figuratively speaking, "scoops the pool." Is there no "danger to the public" in these methods? Are there no "serious temptations" likewise? Wherein, if we are to accept Dr. Saundby's estimate, lies the inducement to benefit their patients by "further advice" or "expert skill" if it means financial desolation and loss of practice subsequently? We have heard "specialists" (?) complain that cases of cancer, &c., are not sent early enough for operation and thereby the patients' chances are seriously jeopardised. Must we judge the matter after the estimate of Dr. Saundby's letter? Or is the complaint of the "specialist" merely a dodge to get more cases in the doubtful stage to operate on under a financial arrangement beneficial to himself solely? Your readers will please bear in mind that I am simply speculating on lines laid down in Dr. Saundby's letter, in that the medical profession under "serious temptations" will come to "dishonour." I am simply showing the temptations and refuse to be responsible for the deductions.

My method, and that of some others known to me, is to meet the financial position of the patient and at the same time take into consideration the claims of my fellow practitioner and support and help him in actual practice instead of preaching "ethics" at him as "soft music to soothe his agony," the while the rising tide of "specialist-aided" hospital abuse and exclusive profit tariff comes up and drowns him and his paying patients. I want it generally understood that a general practitioner can, without giving offence or be thought a scoundrel, make to a "specialist" just such a request as I have had made to me and have gladly complied with: "I have a patient, suffering from so and so, who needs an operation, who wants it done at home, who says that he or she is willing to pay 'so much' for the whole affair, but that if your fee and my fees come to more, he or she will have to go into hospital. I know he or she is not at all well off and they already have had expense. Can you help us?" My reply is: "Tell your patient that for the sum mentioned you and I will do what is necessary—operation and after-treatment." Where is the "dichotomy" in such an arrangement? Does it not make for the benefit of the patient, bodily and financially? Is it not a gain to the patient, the general practitioner, and even the so-called "specialist" to do the work so that the after-treatment entails little or no trouble and that recovery will ensue without avoidable complications? It must be remembered that where one existed formerly there are a hundred skilled men available. Now, Sir, for want of a proper understanding between public and profession I can assure you that general practitioners are actually being driven to aid and abet hospital abuse and I cannot say that I blame them; in fact I consider it poetic justice. Let the following remark of a general practitioner made to me explain my meaning: "The hospital-man (doctor) works on hospitals purely to suit his own ends, to get into a position to charge big fees, to come to my and my neighbours' patients at high fees for operations which he takes good care to prevent me from doing by keeping the hospital circle a closed ring against me and those like me. He parcels out to each of his set as many appointments per man as he can, in order to keep us out and limit competition and therefore keep prices high. His high fees come out of my practice, and therefore leaves me less and less to draw upon amongst my patients who do pay for what they get. If my patients feel the expense of an illness, they pay *cachets* of 50 centigrammes every evening with food this remedy was continued for several months with occasional intervals. In this way M. Lancereaux and M. Paulesco succeeded in putting an end to the phenomena of vaso-dilatation in the vessels of the head and neck and at the same time to the debilitating nightmares, to the tachycardia, to the exophthalmos, and to the goitre; in a word, they had brought about permanent recovery.

Surgery of the Liver.

M. Quenu has operated in four cases of cancer of the gall-bladder without being able to remove the diseased parts; in three of them he did not proceed beyond exploratory laparotomy, and in the fourth, suspecting the existence of biliary calculus, he sought for the gall-bladder in the midst of a mass of new growth but desisted on perceiving that he had to do with epitheliomatous infiltration. M. Quenu believes that epithelioma often complicates biliary lithiasis and that a systematic histological examination of gall-bladders removed for this cause would often reveal epitheliomatous lesions. According to the statistics published in foreign countries the results of operations for cancer of the gall-bladder are generally rather poor. Nevertheless, in 23 cases of cholecystectomy for cancer there was only one death due to the operation and with several of the patients operated on the prolongation of life was truly remarkable.

Riot at the Clermont-Ferrand School of Medicine.

An acute disturbance occurred on March 9th at the Clermont-Ferrand School of Medicine. Thanks to the influence of the Minister of Public Instruction a new Professor, Monsieur Vigenaud, a radical municipal councillor, had been appointed at the end of December without the ordeal of going through the *concours*. The new professor began his duty on March 6th and the occasion passed off without incident but also without any audience, so to speak, for there were only six students present. On the 9th the students turned up in force and they made such a noise that M. Vigenaud could not get out a word and had to take refuge in a neighbouring lecture room. The students followed him into the room and demanded that he should send in his resignation which he accordingly did on the afternoon of the same day.

"The Roux Hygienic Pipe."

Dr. Roux, the well-known director of the Pasteur Institute, has just gained an action which he brought against two commercial inventors who, to give a scientific flavour to an invention of their own, had brought out a pipe which they called "Pipe Hygiénique Roux." They were sentenced to pay Dr. Roux 2000 francs damages, the designation of the pipe was to be suppressed, and the judgment was to be published in five separate newspapers.

March 9th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Mr. Andrew Carnegie's Gift to the Koch Fund.

To celebrate the twenty-fifth anniversary of Professor Robert Koch's discovery of the tubercle bacillus a committee has been formed with the object of collecting a sum of 1,000,000 marks (£50,000) to be called "Robert Koch Stiftung." The money will be used in encouraging researches bearing on the fight against tuberculosis. Up to a short time ago only 300,000 marks had been collected, so that probably there might have been great delay in realising the committee's purpose had not Mr. Andrew Carnegie contributed a sum of not less than 500,000 marks, thus leaving only a deficiency of 200,000 marks. This balance still remaining to be collected is likely to be subscribed before long as it will be a duty of the rich men of Germany to equal the generosity of Mr. Carnegie. It must be remarked that this is the first instance in which Mr. Carnegie has contributed money to an institution outside America or Great Britain. The *Deutsche Medizinische Wochenschrift*, in commenting upon this gift, calls it a conspicuous example of a noble mind and a typical act of this generous friend of humanity.

Proposed Legislation against Quackery.

It has been already explained in these columns on various occasions that in Germany anybody may practise medicine without possessing a legal qualification provided that he avoids assuming a title equivalent or similar to the titles of duly qualified medical practitioners. The consequence of this state of matters, which has existed since 1869, has been an unlimited increase of quacks of every kind whose advertisements fill many columns of the daily and weekly newspapers. Many attempts have been made by the representatives of the medical profession to induce the Government to change the present legislation, but all their efforts have been unavailing; it was said in the Parliamentary debates on this subject that the German public was intelligent enough to distinguish between qualified and unqualified medical men and that if people preferred to be treated by quacks it was their own business. Of course, these views are in marked contrast to the principles of government followed in Germany in other cases, and in opposition to them it has been argued that unskilful treatment might be injurious not only to the individual patient but to the general public also. For instance, in infectious diseases or syphilis the measures necessary to prevent the spread of the disease might be hindered by the intervention of some quack. The persistent efforts of the medical profession, and especially of the Society for the Prevention of Quackery, have gradually succeeded in convincing the Government and the general public that medical quackery is a social danger, and the Government has accordingly at last introduced a Bill directed against quackery and against the sale of medicines of undisclosed composition. The Bill, however, does not do away completely with unqualified practice; it even gives some legal recognition to unqualified practitioners as a class by providing that they must register their addresses at the offices of the local authority; they must also inform the said authority of the circumstances in which their medical training was obtained, and they must keep books according to a prescribed form. Another paragraph of the Bill forbids unqualified persons to treat patients by letter without examination and excludes infectious and venereal diseases from treatment by them. The administration of narcotic compounds and the use of hypnotism and mystical ceremonies are also prohibited. The authorities are empowered to prohibit an unqualified person from practising if he has evidently injured the health of patients and where he has been convicted by a court of justice. Other paragraphs deal with the sale of patent medicines. The sale of such medicines may be prohibited by the Federal Council when they are prejudicial to health or obviously intended to deceive the public. A special commission in connexion with the Imperial Health Office will inform the Federal Council what patent medicines should in its opinion be excluded from sale in Germany. Advertisers of anti-venereal, or aphrodisiac, or anti-conceptional compounds, or medicinal preparations the composition of which is undisclosed, and those who publish advertisements which are evidently fraudulent, may be punished with a fine not exceeding 3000 marks (£150) or with imprisonment for a period not exceeding one year. This Bill, although a step in advance, is not sufficiently far-reaching, because by making regulations to be observed by unqualified practitioners it gives them official recognition. It thus seems to create a new class of practitioners who, though being below the standard of the fully qualified medical profession, are nevertheless legally entitled to attend patients on complying with certain conditions. It would have been better to go to the root of the evil by absolutely prohibiting the practice of medicine by persons who are not in possession of a full medical diploma and by prohibiting quack advertisements. It is, however, very improbable that such a radical measure would ever obtain Parliamentary assent, for the unqualified persons whose interests would be affected find many influential supporters among Members of Parliament.

March 9th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Cancer of the Uterus and its Treatment.

Dr. Paul Kubinyi, first assistant at the Second Gynæcological Clinic of the University of Budapest, has compiled his clinical experiences with regard to cancer of the uterus in a large and well-illustrated volume of 480 pages. His observations are founded on a vast amount of clinical material which has been utilised in accordance with the latest scientific bracket, which has, of course, the surprising effect of suggesting that any attempt to make cheese out of cow's milk is foredoomed to failure. Happily, my two other analyses of goat's and cow's milk show that I am not ignorant of the proteid value of cow's milk. (The Stevenson and Murphy figures are, proteid in cow's milk, 3·55, as compared with 4·29 in the case of goat's milk).

The appreciative review in THE LANCET has given me much pleasure. If goat keeping is to make the progress in this country which it has made on the continent, with remarkable benefit to the health of children, it must be largely due to the good word of the medical profession. Doctors, on looking into the "case for the goat," realise at once how unanswerable it is.

Especially in rural districts, where so many labourers' families have much less milk than they ought to have, medical patronage of "the poor man's cow" must have considerable effect on the stamina of children.

May I just refer to the prejudice against goat's milk due to an alleged taste? A medical man lately made this objection to goat's milk in my presence. I found that his experience of goat's milk had been gained in Egypt and Italy. I sent him a bottle of milk from my goats and he and his wife were at once converts to goat's milk, drinking it in tea and coffee or alone. Goat's milk never tastes except when the animal which yields it is ill, has had access to garlic, ivy, or some other strong-flavoured food, or has been milked into a foul vessel.

I am, Sir, yours faithfully,
Feb. 29th, 1908. "HOME COUNTIES."

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Milk-supply of the City.

THE reports of the public analysts and the medical officer of health under the Sale of Food and Drugs Acts for the quarter ended on Dec. 31st, 1907, showed that whilst the milk from shippons in the city was free from tuberculosis, on the other hand 20 per cent. of the milk coming into the city from the country was contaminated with tuberculosis. This was eloquent testimony to the administration of the health committee and to the work of the medical officer of health, and was the best possible testimonial to the health of the cows housed in the city, as pointed out by the chairman of the infant-life preservation subcommittee of the health committee. Great credit was due to the Liverpool cow-keepers for the manner in which they had responded to the health committee's requirements. He also advised householders to visit personally those shippons from which they obtain their milk and until the milk-supply from the country was free from disease to insist that milk from Liverpool shippons only was supplied to them, even though more payment were required. The public might be reassured to know that joint action was being taken by several of the great cities in this matter. There was a meeting held in Manchester on Feb. 28th of representatives of Birmingham, Leeds, Manchester, Sheffield, and Liverpool, and resolutions were unanimously agreed to calling the attention of the Local Government Board to the matter with a view to legislation in a Bill which Mr. John Burns was about to bring before the House of Commons. In view of the fact that 20 per cent. of the milk which came into Liverpool from the country was proved to be tuberculous every cow should be licensed. The causes of the country cow being diseased were threefold: first, in consequence of the want of appreciation of their responsibility by landlords in not providing healthy shippons for country cattle; secondly, by a want of cleanliness on the part of farmers; and thirdly, by the rural district councils not putting into force the powers which they possessed in connexion with this matter. The Liverpool city council had led the way in the matter from the first and the chairman was satisfied that the council would not rest until the milk-supply from the country sent into the city was as pure as that supplied by Liverpool cow-keepers.

Liverpool Maternity Hospital.

The annual meeting of the subscribers to the Liverpool Ladies' Charity and Lying-in Hospital, henceforth to be known as the Liverpool Maternity Hospital, was held on March 2nd, at the town hall, under the presidency of the Lord Mayor (Dr. Richard Caton). The report stated that the number of patients in the outdoor department was 1673 as against 1649 in the previous year The number of patients attended in the hospital was 357, as against 295 during the year 1906. In the school of midwifery 54 pupils were trained during the year 1907; 24 of these pupils were, in addition, trained in the hospital as monthly nurses and received certificates of proficiency. The managing committee cordially coöperated in reducing the infant mortality in the city. The matron and midwives sent prompt notification of every birth attended to the medical officer of health, and by arrangement with the Liverpool Ladies' Sanitary Association it was intended that the name and address of each applicant in a specified area should be sent to that association so that the "mother's visitors" attached to it may visit the women and give them timely instruction on health and domestic matters, and endeavour to influence the home conditions for good. The financial condition of the charity showed a deficiency of £660. The Lord Mayor, in moving the adoption of the report, said that the charity was one of the oldest and most valuable in the city. He believed that the staff attended one-eleventh of the total births in Liverpool and they saved an immense amount of suffering and prevented much mortality. He regretted that the charity was not better supported and wished some way could be seen of increasing the income. In the matter of maternity provision Liverpool, with its one hospital containing only 19 beds, compared badly with such towns as Glasgow, which had 80 beds; Manchester, 140 beds; and Dublin, with only one-half the population of Liverpool, 126 beds. Liverpool was making an effort to reduce its high infant mortality and one such means was that charity. On the motion of Professor Wilberforce, seconded by Dr. Henry Briggs, it was decided to adopt in future the name "The Liverpool Maternity Hospital and Ladies' Charity" in the place of the old name, as more expressive of the work of the institution.

The Liverpool Country Hospital for Chronic Diseases of Children.

The annual meeting of the friends of this charity was held on March 3rd at the town hall, the Lord Mayor presiding. As the priority of the hospital would seem to have been challenged, the committee in its report goes to some pains to prove the position of the institution. The report begins with an excerpt from a speech delivered by Sir Edward Russell at the opening ceremony of the institution on Nov. 4th, 1899, in the small ward at West Kirby where the work has been carried on ever since, awaiting the opening of the new hospital at Heswall. Sir Edward Russell's words were: "The hospital, he believed, would be looked upon as a great experiment to be followed in other parts of the country, and he was convinced that if they kept their principle in view it might be the beginning of a national undertaking and that the country at large would realise the importance of so teaching the rising generation that nothing of which science could make a certainty should be left to chance." The prophecy has been truly realised during the year 1907, for London has now followed in Liverpool's footsteps and a home for children suffering from tuberculous diseases has been established in Hampshire, mainly through the endeavours of the ex Lord Mayor of London (Sir William Treloar), who, however, in his appeals which were sent far and wide throughout the country, claimed that no institution for the care of children suffering from tuberculous diseases existed in this country. It is to justify the claims of the founders of this hospital and of the appeals that have been made from time to time that special prominence is now given to the fact that there has been in existence for some eight years such an institution as the Liverpool Country Hospital for Children, comprehensive in its scope, dealing with every form of chronic ailment, tuberculous or otherwise, requiring prolonged treatment, whether medical or surgical, in the fresh air of the country. The committee had the satisfaction of acknowledging two handsome donations of £5000 each from Mr. Holbrook Gaskell and Mr. Andrew Gibson, besides smaller gifts, including £300 for a memorial cot from Mrs. and Miss Mitchell Molyneux. The number of endowed cots is six; there are besides six annual appropriated cots. The splint fund has proved most valuable. The report of the honorary medical staff showed the satisfactory nature of the work done during the past year, and the time is looked forward to when, with the accommodation which the new hospital will afford, a largely increased number of cases will be benefited and the present state of affairs, whereby so many children are two educated Bengalis had themselves and their families inoculated it is true; but it is said, "with these extremely rare exceptions the whole of the inoculations were done on people attracted by the reward of eight annas; beggars, drunkards, victims of the opium, hashesh or cocaine habit—the dregs of the streets." These persons come up again and again, anxious to have the eight annas, and care had to be taken to prevent the inoculation of the same person two or three times a month. They have actually taken to making a round of the wards so as to escape detection. Singularly enough, a beggar who had certainly been inoculated three times in a very short period contracted plague; his "case" history should be worthy of record. Dr. Hossack has a good deal to say on the rat and flea theory; and his remarks should attract particular attention in Bombay. He states that the Calcutta pulex cheopis, the rat-flea, will hardly bite human beings at all, even when it is starved; it does not seem to flourish here either and the spread of plague in seasons of epidemic cannot be traced to it. For the information of the curious it may be noted that pulex irritans, the common household flea, is very rare here but that the dog-flea abounds. Dr. Hossack holds that there is no panacea for plague, and he pins his faith to general sanitary improvement though he would exterminate the rat if he could. Practical conclusions are that there is no panacea for plague and all that can be done is to do as much as is practicable for the extermination of rats, preferably with the aid of special legislation in the matter of building. Disinfection must be carried out preferably with a pulicidal disinfectant, but the only thing on which to place reliance is the very difficult measure of general sanitary improvement. Preventive inoculation must be pressed so far as possible, but until the people display a less antagonistic attitude towards it than they do at present it cannot be counted on much as a practical measure. Research work must be prosecuted more vigorously than it has been in the past and the following are points on which evidence might profitably be collected. Much of the work on fleas in Calcutta has been done during the non-epidemic period; this will have to be confirmed during the epidemic period. Post-mortem examinations must be made to decide whether Hunter's contention is correct that even in man intestinal lesions are common and point to food infection. His feeding experiments might well be repeated here as also the Commission's flea-infection experiments. It is hardly necessary to point out that if such experiments as are suggested are to be carried out there must be some provision of a special plague laboratory in which plague-infected animals may be kept. Some increase in the staff will also be necessary if experiments are to be carried out on such a scale as to produce convincing result.

The Jackal in Bengal.

The Government of Bengal has recently been considering the question whether the jackal is a sufficiently dangerous animal to make it worth while to put a reward upon its head. It is reported that the mortality caused by jackals has at particular times and in particular places been serious but not so great as to induce the Government to take special measures. The mortality referred to has probably in most cases been due to hydrophobia, for the jackal seems to be peculiarly susceptible to rabies. A healthy jackal is rarely dangerous to anything above the size of a fowl but a mad jackal often plays havoc among both men and cattle. Meanwhile the Lieutenant-Governor has given authority to Commissioners to take steps to encourage the destruction of jackals in any locality where, or at any time when, they may become a dangerous pest and has sanctioned the payment of a reward not exceeding eight annas for each animal destroyed. The amount of the reward is not very tempting and in the case of a mad animal it is very inadequate, so there seems little risk of the extinction of the species. The jackal serves a useful economic purpose as a scavenger and in any measures for its destruction this is an aspect of the question that should not be overlooked.

Feb. 20th.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

Union Medical College, Peking.

THE annual professional examinations of the above institution have just been held and out of 47 students who went up 38 were successful in passing. The examinations were conducted by an international examining board composed of some of the medical officers of the legations there, acting in conjunction with the teachers of the various subjects. As one of the examiners of this board I could not fail to be impressed, as were the other members, at the way in which the students answered questions. In anatomy, with the exception of an imported limb and bones, all the teaching is done from models, made in Paris. Waterston's Stereoscopic Atlas of Anatomy was also employed. The students knew their models well but the different structures, nerves, arteries, &c., are much too plain to be as useful as teaching from the *corpus vile* and they will have difficulty later when learning surgery. As long as human dissection is not officially permitted it will not be possible to alter this unsatisfactory state of affairs. The subjects for examination were anatomy, physiology, practical histology, therapeutics, and biology. All of these have been taught entirely in Chinese, the terms used being those of the Shanghai Terminological Committee. It is gratifying to the principal (Dr. T. Cochrane) and his staff that they have such good material to work upon, as the average Chinese student is diligent and assiduous in his studies, while at the same time he is fortunate in being the possessor of a well-developed memory that would be the envy of his foreign contemporaries. The whole system of early education in China is one of memorising thousands of ideograms—one for each word—and thus it comes that his memory is trained to a high pitch from his earliest days.

The China Medical Journal.

Efforts are being made by the Medical Missionary Association of China to bring into line the experiences of medical practitioners all over the empire and there has been much improvement of late in the journal which is issued bi-monthly and is well illustrated, and to which any medical man, be he missionary or not, may contribute. The work of the various post-graduate courses in England and America is showing good results not only in the more scientific way in which diseases are discussed but also in the increased number of men who are *au fait* with the methods of clinical research. The first number of this year contains, among others, an article by Dr. C. K. Roys on the Etiology and Diagnosis of Enlarged Spleen which is so common in the province of Shantung. It formed 14 per cent. of all cases treated by Dr. Roys during the past six months. The average age of those affected was 14 years, and the poor are more often affected than the rich. In no case was any malarial parasite found, and in only 3 per cent. was there any evidence of malaria. Though Manson says of enlarged spleen that "wherever they are common the district is malarious and therefore unhealthy, perhaps to Europeans deadly," Dr. Roys said that Shantung province is very little affected with malaria. No foreign children have had it, and in 25 years there have been only two known cases among European adults, both of whom suffered from attacks previously to arrival in this region. Dr. Roys looks upon malnutrition as the chief exciting cause. The food being limited to millet with no meat or rice is lacking in proteins. None of his cases showed primary anæmia or symptoms of idiopathic blood diseases so often associated with enlarged spleen. Hæmoglobin averaged 50 per cent. and none of the counts made showed a leucopenia as in kala-azar. In the few sporadic cases that have come under the notice of your correspondent in Peking noma oris has been the leading symptom, accompanied invariably by evidence of protein starvation. In another article Dr. R. T. Booth of Hankow cites a case of ligature of the common femoral artery and vein in which no sign of deficient collateral circulation appeared and the patient did well, although he had been admitted to hospital suffering from a granulomatous condition of the penis, a mass of enlarged glands in the right groin, and an ulcerated cavity in the left groin. Complete amputation of the penis and double castration with enucleation of glands in the right groin were effected. It was on lightly scraping the left groin that the ulceration was found to have affected the vessels from which there was a tremendous flow of blood. There was no œdema or coldness of the limb. Dr. R. Ascornet, the Imperial Maritime Customs surgeon at Pakhoi, the southernmost port in China, in his report for part of 1907, makes a point in relation to plague which confirms the recent utterances of Mr. Haffkine and Dr. J. Ashburton Thompson with regard to plague occurring independently of communication of the infection from the sick. An outbreak occurred in Ti-cok—about four miles from Pakhoi—and raged for a month there, causing a heavy mortality, but it was entirely limited to this village of 1500 inhabitants and no case was observed either

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Ulster Hospital for Children and Women, Belfast.

AT the annual meeting of the supporters of this institution held on March 3rd it was reported that 247 children and 92 women had been admitted as in-patients during 1907, while in the extern department 2147 children (including 417 eye cases) and 698 women had attended. 226 maternity cases were delivered, of whom nine were admitted to hospital. Financially, the total income for the year was £1129, while the expenditure for the same time was £1108, leaving a balance of £105. The fund for rebuilding the hospital now amounts nearly to £5000 and an additional equal amount would enable the board of management to start operations. Dr. W. St. Clair Symmers, professor of pathology, in moving a proposition, referred to one great drawback to medical progress in Belfast—the difficulties of obtaining post-mortem examinations, which were rare except when ordered by the coroner, owing to the fact that public opinion was dead against them. He spoke of the educating value of such examinations on the medical profession and hoped in time that there would be a change of opinion on the part of the Belfast public who attended hospitals.

Lady Superintendent of Nurses at the Belfast Workhouse.

The Local Government Board has written to the Belfast board of guardians refusing to sanction the person nominated by the guardians to the above post and requesting them to proceed to make another appointment. At their weekly meeting on March 3rd a motion was carried by 21 votes to 16 to the effect that the Local Government Board should be informed that the guardians had made their appointment to the best of their ability and that they refused to change their views on the matter. All the lady guardians voted against the proposition.

The Belfast Society for Providing Nurses for the Sick Poor.

At the annual meeting of this association held on March 6th it was reported that during the past year the number of cases sent forward for attendance was 168 in excess of the previous year, and as usual consumption and other forms of tuberculous disease head the list, there being a total of 215 of such forms of disease. There were also 100 cases of ulcer, 64 of cancer (only two are noted as recovered), 55 of pneumonia, and in all there were 1291 cases. Financially the income from all sources was £1341, while the expenditure was £1180, leaving a balance of £161 on the right side. It was decided to incorporate the society under the Companies Act.

Treatment of Cases of Fever in Belfast.

The medical practitioners of Belfast have received a note from the superintendent medical officer of health dealing with the above matter. Section 156 of the Public Health (Ireland) Act, 1878, provides that "any expenses incurred by a sanitary authority in maintaining in a hospital or in a temporary place for the reception of the sick a patient who is not a pauper, shall be deemed to be a debt from such patient to the sanitary authority," &c. The expenses referred to, the circular goes on to say, mean the costs of conveying, removing, feeding, providing medicines, disinfecting, and all other things required for patients individually, exclusive of structural or establishment expenses. The public health committee, having ascertained that the lowest sum which would cover these "expenses" would be 12*s.* 6*d.* per week, has given instructions for accounts to be made out and furnished on that basis, but, on the other hand, it will reduce or altogether remit (if necessary) the charges in any case where it is satisfied that the circumstances are such as to justify the reduction or remission of the debt.

The Extensions at Purdysburn Asylum.

A deputation has been appointed, consisting of members of the Belfast asylum committee, to wait on the finance committee of the corporation to obtain the money necessary for carrying out the complete scheme at Purdysburn of the buildings required for the whole asylum on the villa system, the estimated cost being £65,000. The work, it is estimated, will occupy four years and the expenditure will be at the rate of £20,000 per annum for each of these four years. The total cost of the whole scheme of concentration will be £125,000, according to a statement of the chairman of the asylum committee.

Triennial Visitation of Queen's College, Cork.

The triennial visitation of Queen's College, Cork, was held last week by the visitors—viz., Mr. Justice Kenny, President; Sir Rowland Blennerbassett; Dr. J. M. Redmond, President of the Royal College of Physicians of Ireland; Mr. John Lentaigne, Vice-President of the Royal College of Surgeons in Ireland; and Sir John William Moore, M.D. A large number of students were present. Mr. Justice Kenny having opened the proceedings, Professor B. C. A. Windle, President of the College, enumerated various improvements which have been made in the equipment of laboratories and in connexion with the anatomical department, with a view of keeping pace with the progress of science, and he also alluded to a valuable Anglo-Indian library which has been established through the munificence of Lieutenant-Colonel Sexton, a former student of the College. The visitors then proceeded to visit the various departments of the College, and on their return Mr. Justice Kenny, in the course of his address, referred to the highly satisfactory condition of the College and medical school. He also said that the medical visitors considered it desirable that a climatological station for training students, especially medical students, to take meteorological observations should be established in connexion with the splendid physical laboratory.

March 10th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Individual Isolation of Patients in Children's Hospitals.

AT a meeting of the Society for Diseases of Children held on Feb. 19th M. Lesage spoke of the great advantages of the individual isolation of patients and described what had been done on his initiative at the Hôpital Hérold with a view to prevent the patients contracting fresh infections (*contagions intra-hospitalières*) during their stay in the wards. Reconstruction has been in progress at this hospital and provision now exists for the individual isolation of each child in a cubicle with glass sides (*un box vitré*), open at the top but having a door which is kept closed. This arrangement of the wards is by itself sufficient to prevent infection without having recourse to rigorous precautions for the avoidance of contamination by indirect contact. There is no washing of hands or changing of overalls unless they are actually soiled; these precautions are, in fact, unnecessary when nothing more has been done than feeling a pulse or auscultating a patient. The charge nurse (*surveillante*) has been abolished. Each ordinary nurse (*infirmière*) is directly responsible to the principal medical officer for the six cubicles and six children under her care.

Implantation of a Metal Plate after Fracture of the Skull.

At a meeting of the Surgical Society M. Morestin gave some particulars of a case which had been under the care of M. Rouvillois. The patient was a young officer who by falling from his horse sustained a slight wound in the right temporo-parietal region. Although there was no symptom of compression an operation was performed and a fracture was found together with intracranial effusion which was evacuated by trephining. After the lapse of some weeks the patient's condition was satisfactory except for the presence of cranial hernia and an adherent cicatrix. In order to protect the brain against possible accidents M. Rouvillois freed the cicatrix and applied a perforated gold plate which he covered with a flap of skin taken from the back of the head. This operation was followed by recovery which has been maintained up to the present time.

Treatment of Exophthalmic Goitre.

At a meeting of the Academy of Medicine held on Feb. 25th M. Lancereaux and M. Paulesco said that the idea had occurred to them that sulphate of quinine was indicated in the treatment of exophthalmic goitre, because it was a typical vaso-constrictor, and the leading pathological feature of exophthalmic goitre was vaso-dilatation of the vessels of the head and neck. They accordingly administered sulphate of quinine to more than 20 patients suffering from this condition and the effects were excellent. Given in doses from one gramme to one and a half grammes in

&c.). Eight hours after the bite he was put to bed and a liberal dose of whitehouse mixture administered. He developed no further symptoms and was discharged four days later. The patient was an old soldier and had served with Lord Roberts in Afghanistan and never knew fear till the day of his accident. I treated him for snake bite pure and simple, no sign of alcoholism, and must say that his condition warranted heroic treatment as he was in a comatose state."

Vital Statistics.

In the quarter ending June 30th, 1907, the number of births in the Commonwealth was 27,895, of which 1656 were illegitimate. 267 cases of twin births were registered and nine cases of triplets. 14,324 were males and 13,571 were females. During the same period there were 10,707 deaths. Tuberculosis was the most destructive disease, claiming 939 victims, of whom 529 were males and 410 females.

Enteric Fever in Victoria.

A return just placed before the Board of Public Health shows a remarkable diminution in the number of cases in the past ten years. In 1898 there were 5423 country cases and 2020 cases in Melbourne, while last year the figures were 1030 and 350. The metropolitan sewerage system has greatly improved the figures for Melbourne.

Remarkable Occurrence.

While two lunatic patients were being taken by steam launch from Sydney to Gladesville Asylum, which is on the Parramatta River, one of them suddenly jumped overboard. Before the attendants grasped the situation the other patient had dived after the first and seizing hold of him kept him afloat till both were rescued by the launch party.

Obituary.

The death is announced of Dr. James Barrett, one of the oldest and most widely known of the older generation of medical men in Melbourne. Dr. Barrett was a native of Banbury, Oxfordshire, and arrived in Melbourne in 1858. He was one of the original members of the Alfred Hospital staff and for many years held a commission as justice of the peace. Three sons are members of the medical profession—viz., Dr. J. W. Barrett who is lecturer on physiology of the special senses at the University of Melbourne and was formerly demonstrator at King's College, London; Dr. Edgar A. Barrett; and Dr. John Barrett who was a distinguished cricketer and visited England as a member of an Australian eleven. One daughter, Dr. Edith Barrett, has also been practising medicine for some years in Melbourne.

Jan. 25th.

Obituary.

REGINALD HARRISON, F.R.C.S. ENG.,

CONSULTING SURGEON TO ST. PETER'S HOSPITAL FOR STONE, ETC.

THE unexpected death of Mr. Reginald Harrison has removed one who for 40 years played a hard-working and distinguished part in two great circles of surgical activity and who devoted his thought and time in no small degree to the alleviation of an unnecessary cause of suffering in city streets with which his hospital experience had early made him familiar.

Reginald Harrison was born 70 years ago in Shropshire and was the eldest son of the late Rev. Thomas Harrison of Stafford. He was educated at Rossal and received the rudiments of his medical training at the Stafford General Hospital where he came under the influence of the late Mr. Moreton of Tarvin, to whose instruction he was wont to acknowledge his lasting debt. Coming to London, he entered St. Bartholomew's Hospital and qualified M.R.C.S. and L.S.A. in 1859. He at once went to Liverpool, the city which was to become the nurse of his professional fortunes, although when he entered it he had not, in his own words, "the acquaintance of one professional friend in the city or neighbourhood." He started as house surgeon at the Northern Hospital and in the next year obtained the valuable appointment of resident surgeon to the Royal Infirmary, a post which he held for three years; at the end of this period he commenced practice but was able to devote much of his time to the remodelling of the Liverpool School of Medicine which had fallen into a very unstable condition. He was appointed demonstrator of anatomy and registrar in the school and shortly afterwards surgeon to the Northern Hospital. In 1866 he became a Fellow of the Royal College of Surgeons of England and two years later he was made assistant surgeon to the Royal Infirmary at Liverpool, succeeding to a full surgeoncy in 1874, and to the senior surgeoncy on the retirement of Mr. E. R. Bickersteth 14 years later. Harrison proved himself to have two qualities which, when they occur in one man, of necessity make for his success: he was an enthusiast and a steady worker. He has left a record of the latter fact in the Liverpool Hospital Reports, of which he was part editor from 1867 to 1871, and he performed a similar duty for the Liverpool and Manchester Reports from 1873 to 1878. During these years other duties were crowding upon him; he was made successively lecturer in Surgery and Anatomy at the Liverpool School of Medicine and in Clinical Surgery at the Victoria University which had not yet undergone its analytical reconstruction. He was also an examiner in surgery at the University of Durham as well as at his own.

In 1883 he was chosen to deliver the Address in Surgery at the Liverpool meeting of the British Medical Association and in 1888 he became President of the Liverpool Medical Institution. In that year he was asked to deliver the Lettsomian Lectures before the Medical Society of London, and he took for his subject "Some Points in the Surgery of the Urinary Organs." By this time he was in the enjoyment of a wide consulting and operating practice, especially in urinary surgery, the branch in which he had taken a special interest from the outset of his career. It was more a matter of regret than surprise to his colleagues, therefore, when in the next year he was invited to go to London to fill the place of the late Mr. Walter Coulson as surgeon to the St. Peter's Hospital for Stone. He accepted the invitation and at his departure from Liverpool was presented with an address and pieces of plate, the presentation being made by the late Sir W. Mitchell Banks. Sixteen years later Harrison returned to Liverpool to do public honour to the memory of that same distinguished surgeon who had been his close personal friend, the occasion being his delivery of the first Banks Memorial Lecture. He took for his subject "The Prospects and Retrospects of University Life," and in the course of a graceful tribute to his departed colleague he showed his deep knowledge of the records of his own university, of the court of which he was a life member. Whilst at Liverpool he married Jane, daughter of Mr. A. Baron, of that city. Harrison came to London with his reputation made and from the first his success in private practice was assured. He continued to play a prominent part in professional life and held many offices; he was made a Vice-President of, and Hunterian professor to, the Royal College of Surgeons in 1890, and Bradshaw lecturer in 1896, when he took for his subject "Vesical Stone and Prostatic Disorders." In the same year he was elected President of the Medical Society of London and gave his official address on "The Treatment of Some Forms of Albuminuria by Renipuncture." Two years later he was made a Vice-President of the Royal Medical and Chirurgical Society, and in 1902 he delivered the annual memorial lecture of the Hunterian Society. This was by no means his last official public utterance, for in 1904 he practically founded the Metropolitan Street Ambulance Association and since then until his death the presidency of that body was a labour of love with him. His interest in ambulance work dated back to his hospital days at Liverpool and he made a careful study of all the systems employed, so that he became an acknowledged authority on ambulance work in civil life. He published a book on the subject, which is in its sixth edition, but his ideals took more solid form than ink and paper.

We need not rehearse all the phases of the movement of which he was the guiding spirit, for we have made frequent allusion to the street ambulance problem for London, and need only refer to a leading article on the subject in THE LANCET of Nov. 23rd, 1907, p. 1474, for an epitome of the whole matter; but we may repeat that Reginald Harrison has been the mainspring of the movement and the fulfilment of his scheme for a motor ambulance service, in so far as it affects the City of London, was a fitting reward for his labour. He was keenly interested in the outcome of the Parliamentary Committee which still has the matter in hand and we wish he could have died assured that it will lead to the extension of the City's system to the whole metropolitan area. His delight was unmistakeable on the two occasions during last year of the public trials of the "White Swan" of the City, as the ambulance car has been dubbed, for the successful investigations. Dr. Kubinyi having been for a long time connected with the clinic has personally attended almost all the cases referred to in his work. His chief, Professor Tauffer, was the first surgeon in Hungary who performed total extirpation of the uterus. Since the first operation 121 total extirpations have been made; out of these about 20 were performed by Dr. Kubinyi himself. The operations were fairly successful, the mortality being only 14 per cent.; due regard must also be had to the fact that many of the cases were very advanced. The decline of the death-rate of the operated cases was noticeable from year to year. As to the technique of the operations, Dr. Kubinyi says that both his chief and himself adhere to the use of the large artery clamps (angioclast), although it cannot be denied that this instrument has some drawbacks, especially the frequent occurrence of secondary hæmorrhages. Amongst the 121 operations there were various complications—namely, lesions of the bladder in eight cases, lesions of the ureter in six cases, and lesions of the rectum in four cases. Dr. Kubinyi finds that the use of the angioclast considerably shortens the duration of the operation. The average time occupied by the operation was from 15 to 20 minutes. In the concluding portion of his work he criticises the methods of teaching at present followed in the University. He maintains that it is unfair always to blame the practitioners for the neglected cases which come under the surgeon's care when they are either inoperable or offer only a very slight hope of success. It would be more reasonable to blame the defective educational system under which the students gain merely theoretical knowledge and attend patients before they have had sufficient practical training. As long as 150 students are crowding the operating theatres it cannot be expected that they will become successful practitioners, on whose shoulders rests the solution of the whole cancer problem. If the practitioner recognises a uterine cancer in its initial stage and sends the patient at once to a surgeon, then the best chances of recovery have been insured.

The Sick-Club Question.

On Feb. 23rd the medical officers of the sick clubs held a meeting in order to arrive at a final decision in the conflict between the clubs and the medical officers. The chair was taken by Dr. Nándor Flesch, chief secretary of the Hungarian Medical Association. On account of the presence of a great many country practitioners at the meeting Dr. Flesch related the history of all the negotiations between the clubs and the special committee of the Medical Association. He said that in spite of every effort the committee could not come to an agreement with the managers of the clubs, partly because the fees offered are exceedingly low—3 kronen (*2s. 6d.*) as compared with the 6 kronen which were asked—and partly because the managers of the clubs would not allow the medical men a free hand in strictly medical affairs. For these reasons Dr. Flesch advised the committee to abstain from any further negotiations with the club managers. It will be much more convenient to let every district branch of the Medical Association negotiate with the local clubs. It was, however, unanimously resolved to send an ultimatum to the clubs informing them that if they do not on or before March 15th agree to pay 6 kronen per member then the medical officers will declare a strike.

Popular Lectures on Hygienic Subjects.

At the last meeting of the Society for the Propagation of Science Dr. Bród Miksa read a paper on the Deficiency of House Accommodation in Budapest. He said that he had had measurements made of the dwellings of 1604 sick members of the Budapest District Sick Club and had collected authentic data about the conditions of living of several thousand workmen inhabiting these places—namely, their yearly income, their rent, the state of their health, and the number of rooms and cots. Dr. Bród Miksa made some terrible disclosures about the miserable condition of these unfortunate people. His investigations showed that only 53 per cent. of the workers possess beds; the others lie on sacks of straw, and in many cases even on the bare floor. Many have to share their beds with two or three others, healthy and sick together. He even found a working woman who had to share her bed with a strange woman immediately after confinement. Not a single workman was found who could claim to have a daily income of 5 kronen (something over *4s.*); needlewomen earn an average of *2s.*, and factory workers *1s.* As to food, only 22 out of 100 workmen have meat every day; most of the workmen live on vegetables, bacon, and flour puddings. Wine is very little consumed by them, strong alcoholic beverages being more used.

The Symptomatological Importance of the Percussion Note given by the Vertebral Column.

Dr. Frederick Korányi, professor of clinical medicine at the University of Budapest, delivered a very interesting address on the above subject at a meeting of the Royal Medical Society. He said that the percussion note of the vertebral column where it covered healthy organs was decidedly different from that elicited when the organ behind it was pathologically changed. He exhibited a case of pleuritic effusion, on which he demonstrated the trigonum pleuriticum (a dull area) discovered and named by himself. He had very satisfactory results with his percussory method in cases of abdominal and pelvic tumours and other malformations. He then demonstrated his method of examining the vertebral column and showed that absolutely typical percussion notes could be elicited on the lumbar, sacral, and coccygeal portions of the column. He also demonstrated the pathological difference of the percussion notes on patients brought from the Gynæcological Clinic. He showed on these patients how the note changed in cases of parametritic exudation, displacement of the uterus, and uterine tumours.

March 7th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Plague and its Treatment in Calcutta.

THERE have never been in Calcutta epidemics of plague such as have swept through the crowded quarters of Bombay and the bazaars of Poona, though in 1900 the disease threatened to extend to Calcutta in an alarming way. But that was the worst year, and since then the incidence of the disease has been comparatively slight. This phrase is used advisedly, for there have been 50,000 deaths in all in the last ten years. This may seem a heavy mortality, but the figures for Bombay city make this bill of mortality appear a small one. Whatever the reason may be plague does not take a great hold upon this city and the sanitary improvements carried out in the worst quarters have unquestionably done much to prevent really severe epidemics since 1900. In an interesting report just presented by Dr. W. O. Hossack, special health officer, this point is clearly brought out, for the two wards which used to suffer most showed last year cases only of 1 in 123 and 1 in 140 of the total population. Formerly the figures were 1 in 47 and 1 in 64. We read that "all the bad *'basti'* centres in these two wards have been cleared out and many of the old and insanitary masonry houses opened up, remodelled, repaired, and put in a proper sanitary condition." A practical commonsense policy has in fact been followed and the general health of Calcutta must have benefited in consequence. It is in the miserable mud huts and Kacha dwelling houses that the disease appears most often. Over 71 per cent. of cases came from these last year, and if we could rebuild the whole native city plague would not get any foothold here. There may be something in the climate and the soil which is inimical to the bacillus, for disinfection has the most remarkable results—the average number of cases per infected house last year was only 1·11. Given fairly healthy surroundings and the poorest classes even in Calcutta need not apparently dread plague. With regard to preventive measures, apart from the sanitary measures taken, there has been a war waged against rats, but it is doubtful whether any great impression has been produced upon these vermin. Upwards of 122,000 were killed last year, but these figures are not impressive when we think of the 4,000,000 rats destroyed by the Japanese in Tokio in three years. It is in the northern parts of the city that most have been killed and it is here that the greatest stores of grain are kept. Until the store-rooms are of good masonry the rats will increase and multiply, as they have ample food supplies upon which to live. In the European quarters their numbers are said to have diminished greatly and the big livery stables in Dharamtollah have practically been purged of their presence. When we get rat-proof godowns for food grains—and such are now being built in some parts of the town—greater success will be gained in the operations in this particular direction. As to inoculation as a prophylactic measure the population as a whole has shown an indifference which is rather disheartening. Some 3100 persons were inoculated last year as against 101 in 1905–06, and at first sight this increase would seem to be satisfactory; but Dr. Hossack has no illusions on the subject. A few Europeans and one or

Medical News.

TRINITY COLLEGE, DUBLIN.—At the Final Examination in Medicine in Hilary term the following candidates were successful :—

Part I.—John L. Phibbs, Frederick A. Anderson, Desmond Drew, and Wellesley R. Allen.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Paul Knapp has been recognised as *privat-docent* of Ophthalmology.—*Berlin:* Dr. Emil Abderhalden, *privat-docent* of Physiology, and Dr. A. Hildebrandt, *privat-docent* of Surgery, have been granted the title of Professor.—*Bologna:* Dr. Giovanni Rubinato has been recognised as *privat-docent* of Internal Pathology.—*Bonn:* Dr. Binz, Professor of Pharmacology, is retiring at the age of 75 years.—*Breslau:* Dr. Wilhelm Harttung of the dermatological department in the Allerheiligen Hospital and Dr. Keller, *privat-docent* of Children's Diseases, have been granted the title of Professor.—*Budapest:* Dr. Karl Hudovernig has been recognised as *privat-docent* of Neurology and Mental Diseases.—*Göttingen:* The title of Professor has been conferred upon Dr. Adolf Jenckel, *privat-docent* of Surgery.—*Heidelberg:* Dr. von Wasielewski, *privat docent* of the Cancer Institute, has been appointed Extraordinary Professor.—*Jena:* Dr. Karl Wittmaarck of Greifswald has been appointed Extraordinary Professor of Otology.—*Kiel:* Dr. Reiner Müller has been recognised as *privat-docent* of Hygiene and Bacteriology; Dr. Friedrich Bering as *privat-docent* of Dermatology; and Dr. Oskar Wandel, *privat-docent* of Medicine, has been granted the title of Professor.—*Leipsic:* Dr. Ernst von Brücke has been recognised as *privat-docent* of Physiology and Dr. Max Versé has been recognised as *privat-docent* of Pathological Anatomy.—*Lemberg:* Dr. Adam Salowij, *privat-docent* of Gynæcology, Dr. Roman Rencke, *privat-docent* of Medicine, and Dr. Edmund Biernacki, *privat-docent* of Experimental Pathology, have been granted the title of Extraordinary Professor.—*Leyden:* Dr. F. Basenau has been recognised as *privat-docent* of Hygiene.—*Marburg:* Dr. Rudolf Hücker of Greifswald has been recognised as *privat-docent* of Surgery.—*Montreal (Laval University):* Dr. Loir has been appointed Professor of Medicine.—*Munich:* Dr. L. Neumeyer, *privat-docent* of Anatomy, has been granted the title of Professor.—*Naples:* Dr. Ettore Pasini and Dr. Michele Scinti have been recognised as *privat-docenten* of Neurology and Psychiatry.—*Pisa:* Dr. Giovanni Pellizzi, Extraordinary Professor of Psychiatry, has been promoted to the Ordinary Professorship.—*Prague (Bohemian University):* Dr. W. Mladejovsky, *privat-docent* of Balneology and Climatology, has been granted the title of Extraordinary Professor.—*Rome:* Dr. Nicola Pende has been recognised as *privat-docent* of Internal Pathology and Dr. Roberto Terzaghi as *privat-docent* of Dermatology.—*Tübingen:* Dr. Johann Jacobj of Göttingen has been appointed to the chair of Pharmacology and Dr. A. Mayer has been recognised as *privat-docent* of Midwifery and Gynæcology.

MEDICAL SOCIETY OF LONDON.—The 135th anniversary dinner of the Medical Society of London was held at the Whitehall Rooms of the Hôtel Métropole, London, on March 11th, the President, Dr. J. Kingston Fowler, being in the chair. Covers were laid for over 130 guests and the proceedings were marked with much enthusiasm. On the right of the chair were seated Prince Francis of Teck, Sir Thomas Barlow (President of the Clinical Section of the Royal Society of Medicine), Mr. R. Marcus Gunn (President of the Ophthalmological Society), Dr. J. B. Ball (President of the Laryngological Section of the Royal Society of Medicine), Sir Anderson Critchett, Sir Felix Semon, Sir Edgcombe Venning, Dr. F. de Havilland Hall, and Mr. A. Pearce Gould. To the left of the chair were Lord Montagu of Beaulieu, Professor W. Osler, Mr. D'Arcy Power (President of the Harveian Society), Dr. C. E. Beevor (President of the Neurological Section of the Royal Society of Medicine), Dr. H. R. Spencer (President of the Obstetrical Section of the Royal Society of Medicine), and Dr. R. J. Probyn-Williams (President of the Society of Anæsthetists). The Chairman, in proposing the toast of "The Medical Society of London," said that the society still retained all its original vitality; the dire misfortune which some had foretold would happen to it in consequence of a certain amalgamation of societies had not occurred. The members of the society now numbered nearly 800 and the attendances at the meetings were most satisfactory. Some of the distinguished Fellows who had resigned by reason of certain changes in other societies had since rejoined the Medical Society. Mr. Edmund Owen in a witty speech proposed the toast of "The Guests and Kindred Societies." Sir Thomas Barlow, who replied to the toast, said that all the societies were of one kith and kin, working together for the honour of the medical profession. They must all admit the premier position of the Medical Society and must acknowledge that it had deserved well of the profession, for in season and out of season it had worked for the unity of the medical profession. Professor Osler, who also replied, referred to the literary treasures contained in the library of the Medical Society of London. He suggested that the diary of the Rev. John Ward should be published, and mentioned that it recorded a meeting of Shakespeare, Ben Jonson, and Drayton when Shakespeare took too much wine and afterwards contracted a fever from which he died. Mr. Pearce Gould proposed the toast of "The President" which was suitably acknowledged, and the proceedings terminated.

SUSSEX COUNTY HOSPITAL.—We have received from Dr. F. G. Bushnell and Dr. A. W. Anderson a summary of the recent work done in the pathological department (the Stephen Ralli Memorial) of this hospital, from which we extract the following particulars. Between August 31st, 1907, and Jan. 31st, 1908, 482 examinations have been made, of which 177 were histological, 20 chemical, 186 bacteriological, and 99 microscopical. 675 media tubes were inoculated and amongst other interesting work tubercle bacilli were found in pleural effusions and the bacillus typhosus was isolated from typhoid dejecta. The parasites which were identified included bilharzia hæmatobia, echinococcus cysts, and spirochæta pallida. The opsonic index was repeatedly estimated in 38 cases and seven bacterial vaccines were prepared. The observers state that "this treatment of staphylococcal infections, especially if subacute or chronic, is hopeful." Necropsies have been performed to the average number of 150 per annum, with the consequent bacteriological and histological investigations. The department has a branch for the assistance of private practice. Since the foundation of the memorial some 30 original contributions have been made to medical literature by research workers in the department. Dr. Anderson is shortly proceeding to Hamburg to demonstrate the technique of opsonic determination in the laboratory of Professor Unna.

ASSOCIATION OF CERTIFICATED DISPENSERS.—The annual meeting of this association was held in the Court-room of the Apothecaries' Hall, Blackfriars, E.C., on March 5th, and was well attended, most of those present being engaged in the Poor-law infirmaries and out-door dispensaries, general and special hospitals, and general dispensaries in London. Mr. Montagu Smith (Lewisham Infirmary) presided. The minutes of the first annual meeting were read and confirmed. The treasurer, Mr. A. L. Anderson (Whitechapel Infirmary) presented the balance-sheet which, after meeting all liabilities, showed a favourable balance of £24 6*s.* 9*d.* The honorary secretary, Mr. A. Howell (Dalston Dispensary), presented the annual report, which stated that the association continued to prosper, the membership having increased by 50 compared with the preceding year, making a total of 225. The committee had kept in close touch with all matters affecting the interests of the members. A deputation had waited on the master and wardens of the Society of Apothecaries, pointing out several urgent and necessary reforms the adoption of which would greatly enhance the value of the assistant's certificate. The introduction of a Bill into Parliament on behalf of the assistants will stand over until it has been seen what can be done for them through the Government Poisons and Pharmacy Bill now before Parliament. The register kept by the honorary secretary had been the means of a large number securing temporary or permanent engagements and members were invited to make their holiday arrangements in good time in order to be provided with trustworthy locum-tenents. It was then announced that if the necessary arrangements could be made a quarterly journal would be instituted and that the next general meeting would be of a social character to enable the members to meet and to know each other better. An appeal to those present on behalf of at Pakhoi or in any of the surrounding villages. He adds: "Il est étonnant que vu le mouvement continuel et très important d'échange qui se fait entre cette ville et Pakhoi, cette dernière soit restée complètement indemne."

The Opium Habit.

In the eyes of those of us in China who are best able to judge the British Government is doing its utmost, so far as is reasonable and fair, to suppress the opium traffic. China also seems in earnest and the recently opened Government bureau for the suppression of opium-smoking is beginning to make itself unpleasantly felt among those habituated to the drug. In England where the liberty of the subject is such a frequent cry when any attempts are made to ameliorate the lot of the people an outcry would soon result if the following methods were followed for putting down alcoholism. I refer to a supplementary set of regulations which have been issued by the bureau in question which now requires that all smokers under the age of 60 years shall take out a licence quarterly which shall not be transferable and which must each time it is renewed state that it is for a smaller amount of opium than the former permit and, further, that no smoker shall apply for the same amount for more than ten consecutive days. In this way it is estimated that the habit should be altogether overcome in the course of from three to six months. Smokers can only obtain the drug from licensed shops and must always obtain their supplies from the same shop, so that their consumption can be checked. They must always carry their permits and present them when purchasing opium and the shops are also required to send in monthly returns showing the amount sold by them each day. Travellers can obtain their supplies from the hotel-keepers who will be held responsible for their customers and who will be granted supplies on specially issued travellers' permits. Smokers of more than 60 years are allowed a free hand! These regulations are for this province (Chih-li) where the evil is not so great as it is down south.

Feb. 5th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Severe Heat Wave.

A HEAT wave of unusual severity and almost unexampled duration passed over South Australia and Victoria between Jan. 13th and 20th. Although the thermometric readings were higher in Adelaide the heat was most trying in Melbourne. The maximum shade readings at the Melbourne Observatory were 109·2° F. on Jan. 17th and 107·6° on Jan. 20th. From the 15th to the 20th the daily maximum in the shade was well over 102°. On Jan. 17th a carefully observed thermometer in the city stood at 112° in a louvred shade box on the roof. Inland some very intense heat was experienced. Over 100 deaths are reported from various parts of Victoria as directly attributable to the heat. At the Melbourne Hospital 23 cases of heat apoplexy were admitted, of which 15 were fatal. Fatalities occurred chiefly among elderly persons and infants. The duration of such intense heat for six days has not a parallel in the Victorian record, though a somewhat similar spell occurred in 1898 over a period of five days.

Australasian Medical Congress.

The arrangements for the congress to be held in Melbourne in October, 1908, are well forward. In the section of medicine special attention will be given to the Conditions of Anæmia which occur in Australia and the Types of Tuberculosis with reference to Sanatorium and Tuberculin Treatment and the Value of Opsonic Indices. In the section of surgery a special discussion will be held on the Surgery of Nerves and Paralysis, opened by Mr. H. S. Newlands of Adelaide and Dr. Basil Kilvington of Melbourne. The Surgical Diseases of the Bile-passages and Pancreas will be discussed by Dr. H. V. C. Hinder of Sydney and Dr. W. Anstey Giles of Adelaide. The Surgery of Non-malignant Disease of the Stomach will receive special consideration from Dr. T. H. Fiaschi of Sydney, Dr. J. Ramsay of Launceston, Tasmania, and Mr. W. H. Brown of Colac, Victoria. Septic Peritonitis and its Surgery will be reviewed by Dr. W. Chisholm of Sydney and Dr. R. B. Duncan of Kyneton, Victoria. Dr. Zwar will deal with Spinal Anæsthesia. The principal general discussions in the section of obstetrics will centre around the question of Premature Termination of Pregnancy; the Early Recognition of Pelvic Infectious Processes of the Puerperium; Eclampsia; Uterine Fibroids; and Dysmenorrhœa. In the diseases of children section Infantile Paralysis, Tubercle, and Rickets will be given special place, while the prevention of introduction of infectious diseases into children's hospitals has also been set down for general discussion. In all the remaining sections interesting work has been arranged and the congress promises to be as successful as any of the previous gatherings.

The Plague

Plague has reappeared in Sydney rather earlier than usual this summer. Up to Jan. 18th three cases have occurred. The disquieting feature of the outbreak is that it has taken place in a part of Sydney which has been hitherto unaffected. The first cases occurred in the vicinity of a produce store in the suburb of Marrickville. The dwellings from which the cases were removed were comfortable artisan cottages and were well kept. Plague rats had been discovered under the produce store and it is surmised that an infected rat may have been conveyed thither in a consignment of chaff which had come from Darling Harbour—a spot where plague rats are frequently discovered. Vigorous measures have been taken by the authorities. None of the cases have proved fatal.

Retiring Officers.

Dr. Woodward, the Government medical officer to the tramways and railways of New South Wales, is about to retire after a lengthy term of service. Dr. Woodward was an Imperial medical officer with a rank of surgeon-general and was appointed to his present position in the railway service in 1883. He was extremely popular and his organisation of the Railway and Tramway Ambulance Corps has been most successful. He compiled a text-book on ambulance soon after his appointment and this has run through five editions.—The city coroner of Melbourne, Mr. Candler, retired on Dec. 31st of last year after a continuous service extending over 54 years. Mr. Candler was born in 1827. His first appointment was in the early days of the "diggings," but he has been in office in and around Melbourne for more than 40 years. The Victorian Government has announced that Mr. Candler will be granted a pension. Many years ago Mr. Candler published monographs on "Consumption" and "Measles," but the views expressed as to etiology have been discounted by the advent of bacteriological science. He is the oldest surviving member of the Melbourne Club.

Alleged Conspiracy.

In September of last year a practitioner at Kalgoorlie, Western Australia, obtained a judgment for £200 damages against four fellow practitioners for alleged conspiracy against him in his professional calling. The full court has since set aside this judgment and entered judgment for the defendants with costs. The chief justice in the course of his judgment said: "No medical man was compelled to associate with any other practitioner. Two or more practitioners were at liberty to combine not to meet another as long as their object was not to injure the latter in his professional calling. Had it been proved that this was the object of the combination it would have contained an element of illegality necessary to conspiracy; as this had not been proved the verdict of the jury and judgment for plaintiff would be set aside." A stay of proceedings was granted till February to enable the plaintiff to ask leave to appeal to the High Courts.

Vicarious Snake Bite.

A case was reported from Shepperton, Victoria, in which a snake bit a small dog. The owner of the dog in attending to it was bitten by the dog and soon after developed marked symptoms of snake-bite poisoning. Dr. Welchmann, who subsequently treated the patient, kindly supplies the following account of the case. "The history was a little dog had been bitten by a snake and while pouring some whisky down the dog's throat it inserted its teeth between the thumb and forefinger of the left hand. The dog died and the patient was noticed to become drowsy. He was immediately driven off to hospital, stopping at one hotel on the road, where he was given some brandy, but as he was getting very sleepy the dose was not repeated. On arrival at the Mooroopna Hospital the patient was comatose and the pupils contracted. Vigorous anti-snakebite treatment was administered (scarification, strychnine, and locally permanganate of potassium, him "inspector of nuisances." It is proposed that the London name shall be universally used. The promoters of the Bill do not propose to extend its provisions to Scotland or Ireland.

The Eyesight of Army Officers.

The relaxation of the regulations with respect to the wearing of glasses by Army officers is to be raised by a question in the House of Commons at an early date. The suggestion, of course, is that candidates for commissions who at present are disqualified by shortsightedness or astigmatism might be accepted if they were allowed to wear glasses on duty.

HOUSE OF LORDS.

THURSDAY, MARCH 5TH.

Poisons and Pharmacy Bill.

The Earl of CREWE moved the second reading of the Poisons and Pharmacy Bill. He said that the subject dealt with in the Bill was familiar to their lordships and a somewhat similar Bill had been introduced in the House of Commons in a recent session. Describing the scope of the present Bill he said that the first clause dealt with some additions that it was considered necessary to make to the Schedule of Poisons. The second clause enabled certain poisonous substances used for horticultural and agricultural purposes to be sold by dealers who were not chemists where need arose owing to the absence of qualified sellers. The third clause was also important, although non-controversial. It provided that where a chemist carried on business in more than one shop there should be a qualified chemist in charge of each shop. The fourth clause dealt with certain amendments with regard to the examination of the Pharmaceutical Society, and the fifth clause enabled regulations to be made in order to safeguard the sale and distribution of certain poisons commonly employed for domestic and industrial purposes. The Bill differed from the previous measure in the omission of two subjects on which controversy took place. This Bill did not apply to Ireland and he did not desire to trouble their lordships with the pros and cons of that subject now. The other controversial point was, What should be the powers of limited liability companies trading as chemists as regarded the titles which they could use? Ought they to be allowed to describe themselves by such titles as chemists and druggists? Considerable controversy arose in these directions and the Government had not included these matters in the Bill for this reason. There was a sharp line of demarcation of feeling upon both subjects—perhaps more strong in the House of Commons than in the House of Lords. He therefore would propose that if their lordships read the Bill a second time it should be referred to a joint committee of both Houses of Parliament in order that evidence might be taken on the two points to which he had alluded, and then, if the committee desired it, they might make recommendations on them to Parliament. He hoped that the Bill would come back from the joint committee in sufficient time to allow the very valuable uncontroversial clauses to become the law of the land this session, with the addition of such controversial matter as Parliament might think fit.

Lord ASHBOURNE (much of whose speech was indistinctly heard in the Press Gallery) was understood to say that the Bill involved considerations of very general interest and the course suggested by the noble Earl appeared to be convenient. It was possible that although certain matters to which the noble Earl had referred might not be controversial they might still be subjected to a reasonable amount of criticism. He went on to say that the power of addition to the Schedule of Poisons must always be given in such legislation. They could never stereotype the poisons at any particular period. He had no doubt that the Pharmacy Act of 1868 had been added to by Orders in Council just as under the Irish Act of 1870 it had been added to by the appropriate authorities in Ireland. He could not help thinking that the question of Irish legislation could not be left out of view in connexion with the Bill. They in Ireland would like to see the subject of poisons dealt with in a clear and intelligent way, and if there was an improvement in the law of England they would like to have some improvement in the law of Ireland. If it was not found convenient and desirable to adopt the whole Bill in the case of Ireland he could see no objection to saying that the same schedule of poisons which science had found was required for England should be applied to Ireland.

The Bill was then read a second time.

It was agreed, on the motion of the Earl of CREWE, to refer the Bill to a joint committee of both Houses of Parliament.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 4TH.

The Health of the Army.

Mr. HALDANE, in the course of his annual statement on the Army said that since last November the War Office had been paying threepence extra per day to the recruit. The recruit was at a growing stage and there was nothing on which attention had been more concentrated than the improvement of his spiritual, mental, and bodily condition. The result of that policy was that the class of recruits was undoubtedly improving. The consensus of the reports from the various districts was to this effect. The pay, the additional comforts, and the prospects of the soldier were having a marked effect. There were many indications to prove this but perhaps the most satisfactory was the decrease of wastage. Wastage might be comprised under the following heads: invaliding, men discharged within three months of their enlistment as not likely to make efficient soldiers, and men discharged for misconduct. In 1903–04 the number of invalids was 4973; in 1904–05, owing to the efforts of his predecessor, the number fell to 4226; in 1905–06 it was 3234; last year it dropped to 2894; and he had no doubt that this year it was again falling. Having dealt with the discharges for inefficiency and misconduct the right honourable gentleman went on to say that two years ago he was struck with the fact that there was a disease in the army which was known as "soldier's heart." It seemed that the heart of the soldier became more easily affected than the heart of any other class. He had therefore appointed a highly qualified committee of very distinguished medical men and physiologists together with practical officers to sit under the Director-General of the Army Medical Service and to inquire into the whole system of the physical training of the soldier. This committee traced "soldier's heart" to the old-fashioned system of doing exercises and the War Office had substituted for it the Danish system of training. The great advantage under the new conditions was that physical exercises were based not only on military requirements but on medical expert advice as to their effect. The report stated that the new exercises tended to develop the intelligence of the men, that they were capable of being performed without undue distress to them and were more interesting in their nature, and they would undoubtedly diminish admission to hospital for disordered action of the heart. So much for physical exercises. He was glad to say that under other heads things were improving very much. The Director-General of the Army Medical Service reported to him for the purposes of this statement that improvements had already begun to accrue from the steps which had been taken towards the prevention of disease and consequent inefficiency of the army. For instance, whereas the average yearly number of cases of Malta fever was for the years 1896–1905 over 160 in every 1000 men in the garrison, in 1907 the number had fallen to two in every 1000 men. This represented a saving of about 40,000 days' pay in a year to the British Government taking into account only the days spent in hospital and not the loss and expense entailed by death and invaliding. That was, he thought, a remarkable tribute to the achievements of science. This improvement, the report stated, might be directly attributed to scientific discoveries lately made in large part by officers of the department. As a result of the steps which had been taken in consequence of these discoveries the disease might be regarded as practically stamped out. He thought that he ought here to acknowledge how much they owed to this committee and also to the Royal Society for the deep interest it had taken in this matter. The committee also said: "We can also report for the year 1907 a considerable improvement in the health of the British Army in India in respect of three important diseases—enteric fever, venereal disease, and malarial fever. We regard this satisfactory state of affairs as a direct result of the increased attention paid by all the authorities concerned, both military and medical, to sanitation in cantonments. The improvement in venereal disease may be attributed to an increase in temperance and an improvement in general moral tone throughout the ranks of the army." He might say in connexion with the Army Medical Service that the War Department had this year opened a new medical college in London which would, he hoped, greatly facilitate the education of these most valuable officers of the army—the officers of the Army Medical Service. As regarded temperance he had given instructions that wherever it was possible an army tent might be placed at the disposal of the temperance organisation of a battalion and the War Office had taken every step it could to encourage the cause. The growth of temperance in the army was marked and satisfactory. There had been an improvement in dining arrangements and in many other things which conduced to the well-being of the men. The right honourable gentleman then proceeded to deal with other topics.

In the course of subsequent discussion Mr. SEDDON said that unless he was wrongly informed the decrease in venereal disease in the army was not in fact what it was represented to be. He therefore thought that it would be a wise protection if the medical inspection of the soldiers, especially in large towns, was made more minute than it was at the present time.

THURSDAY, MARCH 5TH.

Royal Territorial Medical Corps.

Sir FRANCIS POWELL asked the Secretary of State for War whether Volunteer surgeons on enlistment in the new Territorial forces would cease to be attached to their present regiments; whether they would be gazetted to a Royal Territorial Medical Corps and be required to wear the uniform of such corps; whether the compound title or rank would be abolished; whether the senior medical officer would, if efficient, be appointed brigade surgeon; and if so, while holding the appointment, whether he would be seconded from his regiment.—Mr. HALDANE replied: Medical officers of the Volunteers will have the option of transferring to the Royal Territorial Medical Corps or of remaining regimental officers. Those who transfer will be permitted to retain the uniform of their former unit until worn out. The compound title will be abolished in the case of those who join the Territorial Medical Corps. The appointment of brigade surgeon in the Territorial Force will lapse as the Territorial Force will be organised on the same basis as the regular army, in which such appointment does not exist.

Medical Inspection in Voluntary Schools.

Sir FRANCIS POWELL asked the President of the Board of Education whether, under the proposals of the Government, the cost of the medical inspection of children in voluntary schools would be defrayed from the same sources and administered under the same regulations as in the case of provided schools.—Mr. MCKENNA answered: Yes, sir.

St. John and St. Andrew Ambulance Lectures.

Major ANSTRUTHER-GRAY asked the President of the Board of Trade whether Scotch candidates under St. Andrew Ambulance for masters' and mates' first-aid certificates must attend eight lectures out of 12, while the English candidates under St. John Ambulance had to attend only four and five lectures; and whether, seeing that this system involved more time, trouble, and expense to the Scotch candidate than was deemed necessary for the English candidate, he would take steps to make the two courses equal.—Mr. KEARLEY (Parliamentary Secretary to the Board of Trade) replied: The St. John Association requires a minimum of four lectures of two hours' duration; the St Andrew a minimum of eight lectures of one and a half hours' duration. The expense under the St. John varies from about 12s. 6d. to 17s. 6d., that under the St. Andrew is fixed at £1 1s. We have no power to compel either of these associations to vary its course.

The Investigation of Non-fatal Accidents.

Mr. ARTHUR HENDERSON asked the Secretary of State for the Home Department what number or percentage of the 123,230 non-fatal accidents reported in 1907 were made the subject of special investigation by factory inspectors.—Mr. GLADSTONE answered: The information asked for by the honourable Member is not available and could at Pakhoi or in any of the surrounding villages. He adds: "Il est étonnant que vu le mouvement continuel et très important d'échange qui se fait entre cette ville et Pakhoi, cette dernière soit restée complètement indemne."

The Opium Habit.

In the eyes of those of us in China who are best able to judge the British Government is doing its utmost, so far as is *reasonable and fair, to suppress the opium traffic.* China also seems in earnest and the recently opened Government bureau for the suppression of opium-smoking is beginning to make itself unpleasantly felt among those habituated to the drug. In England where the liberty of the subject is such a frequent cry when any attempts are made to ameliorate the lot of the people an outcry would soon result if the following methods were followed for putting down alcoholism. I refer to a supplementary set of regulations which have been issued by the bureau in question which now requires that all smokers under the age of 60 years shall take out a licence quarterly which shall not be transferable and which must each time it is renewed state that it is for a smaller amount of opium than the former permit and, further, that no smoker shall apply for the same amount for more than ten consecutive days. In this way it is estimated that the habit should be altogether overcome in the course of from three to six months. Smokers can only obtain the drug from licensed shops and must always obtain their supplies from the same shop, so that their consumption can be checked. They must always carry their permits and present them when purchasing opium and the shops are also required to send in monthly returns showing the amount sold by them each day. Travellers can obtain their supplies from the hotel-keepers who will be held responsible for their customers and who will be granted supplies on specially issued travellers' permits. Smokers of more than 60 years are allowed a free hand! These regulations are for this province (Chih-li) where the evil is not so great as it is down south.

Feb. 5th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Severe Heat Wave.

A HEAT wave of unusual severity and almost unexampled duration passed over South Australia and Victoria between Jan. 13th and 20th. Although the thermometric readings were higher in Adelaide the heat was most trying in Melbourne. The maximum shade readings at the Melbourne Observatory were 109·2° F. on Jan. 17th and 107·6° on Jan. 20th. From the 15th to the 20th the daily maximum in the shade was well over 102°. On Jan. 17th a carefully observed thermometer in the city stood at 112° in a louvred shade box on the roof. Inland some very intense heat was experienced. Over 100 deaths are reported from various parts of Victoria as directly attributable to the heat. At the Melbourne Hospital 23 cases of heat apoplexy were admitted, of which 15 were fatal. Fatalities occurred chiefly among elderly persons and infants. The duration of such intense heat for six days has not a parallel in the Victorian record, though a somewhat similar spell occurred in 1898 over a period of five days.

Australasian Medical Congress.

The arrangements for the congress to be held in Melbourne in October, 1908, are well forward. In the section of medicine special attention will be given to the Conditions of Anæmia which occur in Australia and the Types of Tuberculosis with reference to Sanatorium and Tuberculin Treatment and the Value of Opsonic Indices. In the section of surgery a special discussion will be held on the Surgery of Nerves and Paralysis, opened by Mr. H. S. Newlands of Adelaide and Dr. Basil Kilvington of Melbourne. The Surgical Diseases of the Bile-passages and Pancreas will be discussed by Dr. H. V. O. Hinder of Sydney and Dr. W. Anstey Giles of Adelaide. The Surgery of Non-malignant Disease of the Stomach will receive special consideration from Dr. T. H. Fiaschi of Sydney, Dr. J. Ramsay of Launceston, Tasmania, and Mr. W. H. Brown of Colac, Victoria. Septic Peritonitis and its Surgery will be reviewed by Dr. W. Chisholm of Sydney and Dr. R. B. Duncan of Kyneton, Victoria. Dr. Zwar will deal with Spinal Anæsthesia. The principal general discussions in the section of obstetrics will centre around the question of Premature Termination of Pregnancy; the Early Recognition of Pelvic Infectious Processes of the Puerperium; Eclampsia; Uterine Fibroids; and Dysmenorrhœa. In the diseases of children section Infantile Paralysis, Tubercle, and Rickets will be given special place, while the prevention of introduction of infectious diseases into children's hospitals has also been set down for general discussion. In all the remaining sections interesting work has been arranged and the congress promises to be as successful as any of the previous gatherings.

The Plague.

Plague has reappeared in Sydney rather earlier than usual this summer. Up to Jan. 18th three cases have occurred. The disquieting feature of the outbreak is that it has taken place in a part of Sydney which has been hitherto unaffected. The first cases occurred in the vicinity of a produce store in the suburb of Marrickville. The dwellings from which the cases were removed were comfortable artisan cottages and were well kept. Plague rats had been discovered under the produce store and it is surmised that an infected rat may have been conveyed thither in a consignment of chaff which had come from Darling Harbour—a spot where plague rats are frequently discovered. Vigorous measures have been taken by the authorities. None of the cases have proved fatal.

Retiring Officers.

Dr. Woodward, the Government medical officer to the tramways and railways of New South Wales, is about to retire after a lengthy term of service. Dr. Woodward was an Imperial medical officer with a rank of surgeon-general and was appointed to his present position in the railway service in 1883. He was extremely popular and his organisation of the Railway and Tramway Ambulance Corps has been most successful. He compiled a text-book on ambulance soon after his appointment and this has run through five editions.—The city coroner of Melbourne, Mr. Candler, retired on Dec. 31st of last year after a continuous service extending over 54 years. Mr. Candler was born in 1827. His first appointment was in the early days of the "diggings," but he has been in office in and around Melbourne for more than 40 years. The Victorian Government has announced that Mr. Candler will be granted a pension. Many years ago Mr. Candler published monographs on "Consumption" and "Measles," but the views expressed as to etiology have been discounted by the advent of bacteriological science. He is the oldest surviving member of the Melbourne Club.

Alleged Conspiracy.

In September of last year a practitioner at Kalgoorlie, Western Australia, obtained a judgment for £200 damages against four fellow practitioners for alleged conspiracy against him in his professional calling. The full court has since set aside this judgment and entered judgment for the defendants with costs. The chief justice in the course of his judgment said: "No medical man was compelled to associate with any other practitioner. Two or more practitioners were at liberty to combine not to meet another as long as their object was not to injure the latter in his professional calling. Had it been proved that this was the object of the combination it would have contained an element of illegality necessary to conspiracy; as this had not been proved the verdict of the jury and judgment for plaintiff would be set aside." A stay of proceedings was granted till February to enable the plaintiff to ask leave to appeal to the High Courts.

Vicarious Snake Bite.

A case was reported from Shepperton, Victoria, in which a snake bit a small dog. The owner of the dog in attending to it was bitten by the dog and soon after developed marked symptoms of snake-bite poisoning. Dr. Welchmann, who subsequently treated the patient, kindly supplies the following account of the case. "The history was a little dog had been bitten by a snake and while pouring some whisky down the dog's throat it inserted its teeth between the thumb and forefinger of the left hand. The dog died and the patient was noticed to become drowsy. He was immediately driven off to hospital, stopping at one hotel on the road, where he was given some brandy, but as he was getting very sleepy the dose was not repeated. On arrival at the Mooroopna Hospital the patient was comatose and the pupils contracted. Vigorous anti-snakebite treatment was administered (scarification, strychnine, and locally permanganate of potassium, staff of their respective departments should be vaccinated. This opinion was conveyed to the employees in these departments, but it was stated that the committee in no way desired to compel them to be vaccinated against their own wishes. 33 persons as a result had been vaccinated, eight by the public vaccinator and 23 by the deputy public vaccinator. The deputy public vaccinator was, and is, a member of the borough council, but he was not employed by the borough council in this matter, nor has he received from them any fees in respect of it. The employees were at liberty to go to any medical man they pleased, and they went to the public vaccinator or his deputy, because by so doing they were vaccinated free of charge. The usual fee in respect of the operation would be paid by the board of guardians of the parish.

The Ventilation of the House.

Sir PHILIP MAGNUS asked the Prime Minister whether, having regard to the prevalence of influenza among Members of the House of Commons, he would reconsider the advisableness of a daily adjournment of the House for a half hour between the hours of seven and nine in the evening with a view to the better ventilation of the House by the admission of fresh air through opened windows.—Mr. HARCOURT (the First Commissioner of Works) in the absence of Sir Henry Campbell-Bannerman replied: The opening of windows would be a distinct hindrance to the efficient ventilation under the new and improved system. The absence of members might be of advantage at any period of the sitting, but during their presence the whole air of the chamber is changed every five minutes and it is possible, though not comfortable, to do this in three minutes. The more rapid change is invariably effected during divisions when both members and air are in movement.

Sir PHILIP MAGNUS: May I ask the right honourable gentleman whether he has tried the experiment of flushing the chamber with fresh air for a quarter of an hour or 20 minutes during late sittings of the House.

Mr. HARCOURT: Yes, the experiment has been tried but not successfully.

Sir PHILIP MAGNUS: Will the right honourable gentleman say what were the effects? Was there more or less influenza?

Mr. HARCOURT: The effect of opening the windows to admit fresh air was to prevent air being delivered through the floor.

Sir PHILIP MAGNUS: Does the right honourable gentleman consider it a disadvantage that fresh air should be received through the windows rather than through the matting of the floor over which scores of Members tread with dirty boots?

Mr. HARCOURT: The air admitted by the windows is received only by the fans in the ceiling and not by Members on the floor of the House.

The Royal Navy Medical Service.

In the course of the discussion on the Navy Estimates

Mr. MITCHELL-THOMSON said that for some time there had been a complaint about the position, prospects, and pay of the Navy Medical Service. It was time that the Admiralty had inquired to see whether if some revision of the scale of pay was carried out it would have the effect of attracting to the service more higher graduates from the medical schools of the country. He also wanted to draw attention to the importance of giving Navy medical officers an opportunity of studying in the hospitals on shore. He expressed the hope that both these matters would be seriously considered.

Mr. LAMBERT (Civil Lord of the Admiralty) at a later stage of the debate said that of course the Admiralty would most carefully consider these suggestions with regard to the Navy Medical Service.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BEALE, PEYTON T. B., F.R.C.S. Eng., has been appointed Surgeon to the City Dispensary.

BRISCOE, J. CHARLTON, M.D. Lond., has been appointed Assistant Physician to King's College Hospital.

BROWNE-MASON, JOHN THOMAS, L.D.S. Eng., has been appointed Honorary Consulting Dental Surgeon to the Exeter Dental Hospital.

CARR, HAMPDEN, L.K.Q.C.P. Irel., L.R.C.S. Irel., has been appointed Honorary Medical Officer at the Port Pirie Hospital, South Australia.

CROSS, F. G., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Kingston District of the county of Surrey.

DALBY, AUGUSTUS WILLIAM, L.R.C.P. & S. Edin., has been re-appointed Medical Officer of Health for the Frome (*Somerset*) Rural District.

EAGER, RICHARD, M.B. Aberd., has been appointed Senior Assistant Medical Officer at the Devon County Asylum, Exminster.

GIBSON, J. A., M.D. Edin., has been appointed by the Isle of Wight County Education Committee as Medical Inspector of Schools for the County.

HALL, GEORGE, M.D. Lond., B.Sc. Dunelm, M.R.C.P. Lond., has been appointed Honorary Assistant Physician to the Royal Victoria Infirmary, Newcastle-on-Tyne.

HUDSON, BERNARD, M.D. Cantab., M.R.C.P. Lond., has been appointed Assistant Physician to the Royal Hospital for Diseases of the Chest, City-road, E.C.

JAQUES, ROBERT, F.R.C.S. Eng., has been appointed Honorary Surgeon to the Plymouth Royal Eye Infirmary.

JEWESBURY, REGINALD C., M.B. Oxon., M.R.C.P. Lond., has been appointed Assistant Physician to Charing Cross Hospital.

JOHNSTON, W. L., M.B., Ch.B. Edin., has been appointed Resident House Surgeon at the Royal Infirmary, Stirling.

MONTESOLE, M. HERSCHEL, L.R.C.P. Lond., M.R.C.S., has been appointed Junior House Surgeon at the Western General Dispensary, Marylebone-road, N.W.

PARKIN, ALFRED, M.D. Durh., F.R.C.S. Eng., has been appointed Honorary Assistant Physician to the Royal Victoria Infirmary, Newcastle-on-Tyne.

RIGGALL, ROBERT MARMADUKE, M.R.C.S., L.R.C.P., has been appointed Second Assistant Medical Officer at the Devon County Asylum, Exminster.

ROCYN-JONES, DAVID THOMAS, M.B., C.M. Edin., D.P.H. Oxon., has been appointed Medical Officer of Health and Medical Inspector of Schools for the County of Monmouthshire.

SILVER, CLIFFORD MARKING, L.D.S. Eng., has been appointed Dental Surgeon to the Exeter Dental Hospital.

WATKINS, JOHN G., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer by the Taunton Board of Guardians.

WHARTON, JOHN, M.D., B.C. Cantab., has been appointed Honorary Assistant Surgeon to the Manchester Royal Eye Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BANGOR, CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House Surgeon. Salary £80 per annum, rising to £100, with board, washing, and lodging.

BIRMINGHAM, JAFFRAY BRANCH OF THE GENERAL HOSPITAL, Gravelly Hill.—Resident Medical and Surgical Officer. Salary £150 per annum, with board, residence, and washing.

BIRMINGHAM, QUEEN'S HOSPITAL.—Two House Physicians for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

BOURNEMOUTH, ROYAL NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST.—Resident Medical Officer. Salary £10 per month, with board, residence, and washing.

BRADFORD ROYAL INFIRMARY.—House Physician and House Surgeon, unmarried. Salaries £100 per annum, with board and residence.

BUCKS COUNTY COUNCIL.—Medical Officer of Health. Salary 50 guineas per annum and fees.

BUCKS COUNTY EDUCATION COMMITTEE.—Education Medical Officer. Salary £300 per annum, with expenses.

BURY, CORPORATION OF.—Assistant Medical Officer of Health and School Medical Officer. Salary £150 per annum.

CANTERBURY BOROUGH ASYLUM.—Assistant Medical Officer, unmarried. Salary £140 per annum, with board, lodging, washing, and attendance.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Physician for six months. Salary £30, with board, residence, and laundry.

CARLISLE, CITY OF.—Medical Officer of Health. Salary £500 per annum.

CHORLTON-UPON-MEDLOCK DISPENSARY, Manchester.—Honorary Medical Officer.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, washing, and residence. Also Physician to Out-patients.

COVENTRY AND WARWICKSHIRE HOSPITAL, Coventry.—Junior House Surgeon. Salary at rate of £60 per annum, with rooms, board, washing, and attendance.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—House Surgeon and Assistant House Surgeon. Salaries £80 and £40 respectively, with board and lodging.

DUNFERMLINE, CARNEGIE DUNFERMLINE TRUSTEES.—Assistant Medical Officer (female). Salary £200 per annum.

ECCLES AND PATRICROFT HOSPITAL.—House Surgeon, unmarried. Salary £70 per annum, with board and washing.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—Eight Clinical Assistants.

EXMINSTER, DEVON COUNTY ASYLUM.—Third Assistant Medical Officer. Salary £140, rising to £160, with board, lodging, and washing.

FINCHLEY URBAN DISTRICT COUNCIL.—Medical Officer of Health and Superintendent of the Hospital. Salary £300 per annum, rising to £400.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway, N.—Senior House Surgeon, Senior House Physician, Two Junior House Surgeons, and One Junior House Physician. Salary of Senior Officers at rate of £60 per annum, and of Junior Officers at £30 per annum, with board, lodging, and washing.

HAMPSTEAD GENERAL HOSPITAL, WITH WHICH IS AMALGAMATED THE NORTH-WEST LONDON HOSPITAL.—Three Physicians and two Surgeons in charge of the Out-patients' Department in Kentish Town. Also two Anæsthetists at the Hampstead Hospital.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon for six months. Salary £20. Also House Physician for eight months. Salary 25 guineas. Also Assistant Casualty Medical Officer for eight months. Salary 25 guineas. All with board and residence.

IPSWICH, BOROUGH OF.—Assistant Medical Officer of Health. Salary at rate of £150 per annum.

KENT COUNTY COUNCIL.—Medical Officer of Health. Salary £800 per annum, with expenses.

LEAMINGTON, WARNEFORD, LEAMINGTON, AND SOUTH WARWICKSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, washing, and apartments.

LEICESTER INFIRMARY.—Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

LINCOLN UNION.—Medical Officer. Salary £100 per annum and fees.

LISCARD, VICTORIA CENTRAL HOSPITAL.—Honorary Assistant Anæsthetist.

LIVERPOOL DISPENSARIES.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

institution of which, as our readers will remember, the public owes a good deal to Captain Nott Bower, the Chief Commissioner of the City Police, who was Mr. Harrison's son-in-law. In recognition of his ambulance work he was made a Knight of Grace of the Order of St. John of Jerusalem. Two years ago the Khedive of Egypt conferred upon him the First Class of the Imperial Order of the Medjidieh in appreciation of his services. He was an honorary member of the French Surgical and Urological Society and of more than one similar society in America. He showed his sympathy with distant colleagues by appealing to the profession at home for duplicate copies of books to send to Toronto to replace the medical section of the library after it had been destroyed by fire in 1890.

Such was his public career. In private life he was a kind and courteous gentleman, a man who attracted friends naturally. He was a man of wide tastes outside surgery, and these are well indicated by saying that he was a member of the Athenæum, the Garrick, and the M.C.C. He died at Lower Berkeley-street on Feb. 28th from influenzal pneumonia after a very short illness. He is survived by one son and two daughters. Mr. Harrison was an industrious writer, as our own columns abundantly testify. During the last two decades of the last century there were few years in which he did not contribute some paper of urological interest, so that his papers form a fair epitome of the progress of that branch of surgery. The books which he published, besides those mentioned above, were "The Urethrotomies and Kidney Capsulotomy," "The Surgical Disorders of the Urinary Organs," and "Clinical Lectures on Stone and Urinary Disorders." His occasional contributions, were largely concerned with urethrotomy, the treatment of certain cases of acute nephritis by renipuncture and later by capsulotomy, and the pathology and treatment of enlarged prostate. For long he advocated vasectomy in this last-named condition but in his later writings he gave due consideration to prostatectomy. He maintained a prejudice in favour of the perineal route for lithotomy after the pendulum of opinion had swung towards the suprapubic operation but he was no slave to custom and judged every procedure on what appeared to him to be its merits. As far back as 1888 he demonstrated the electric endoscope at Liverpool and then reminded his audience that 20 years previously he had shown there Desormeaux's primitive instrument with its paraffin illumination. In his Bradshaw lecture in 1896 he showed a keen appreciation of the potentiality of the x rays as a means of diagnosis of stone, a prophesy which he lived to see justified. Amongst other subjects on which he wrote were albuminuria and kidney tension, lithotrity, and urine fever. His thoughts, however, were not entirely fixed on his special practice for three years ago he sent us a thoughtful little paper on the possible connexion between the increase in appendicitis and the use of boric acid as a preservative of food.

Dr. Richard Caton, Lord Mayor of Liverpool, and an old friend and colleague of Mr. Reginald Harrison, has kindly sent to us the following supplementary note. "The numerous friends of the late Mr. Reginald Harrison, alike those in the profession and among the laity, have heard with the deepest regret the news of his death. In Liverpool the feeling was particularly strong and widespread. The bonhomie, cheeriness, kindliness of nature which characterised Mr. Harrison, no less than his great ability in his own professional sphere, caused him to be greatly beloved and highly valued. The special ability and tact which were so characteristic of him were of great value not merely in the hospitals which he served so diligently in Liverpool, but also in regard to his connexion with the Medical Institution and the School of Medicine. It is well known that Great Britain owed to Mr. Harrison the introduction of the ambulance system. He had noted during his travels in America the great advantages that method offered, and after some difficulty he succeeded in persuading the authorities in Liverpool to institute an exactly similar arrangement. This, as we know, has now been copied in a large number of cities not only in England but throughout Europe, and is found of the greatest advantage. Mr. Harrison's zeal and energy were exceedingly valuable also to the School of Medicine. At a time when that institution was in low water and when it was a matter of doubt whether it was worth while continuing it, Mr. Harrison together with two or three of his colleagues were of opinion that if improved and maintained it might prove the germ from which a college and even a university might spring in the city of Liverpool, and to a considerable extent the present flourishing University of Liverpool has to thank him that its foundation took place at so early a date as it did. Mr. Harrison was greatly beloved by his students. His methods of teaching were simple, direct, and practical. He wasted little time in disquisitions upon theory, but he showed his pupils how to form a careful diagnosis and how to carry out a useful and practical treatment. The loss to Mr. Harrison's private friends is indeed a very great one. Not many men have such kindliness, such capacities for friendship, and few had the wonderful memory that he possessed in regard to faces and individuals whom he had known even at remote periods of time. Nowhere is his loss more lamented than among his many friends in Liverpool."

EDWARD DILLON MAPOTHER, M.D. R.U.I., F.R.C.S. IREL.

THE many friends in England and Ireland of Dr. Edward Dillon Mapother, and those Irishmen scattered through the world who were his former pupils at the Royal College of Surgeons in Ireland will regret to hear of his death which took place at his residence, 16, Welbeck-street, London, W., from influenza and broncho-pneumonia, on March 3rd, in his seventy-third year. He had retired from active practice for several years and had lately been in failing health.

Dr. Mapother belonged to a well-known Roscommon family of English descent but long settled in that county. He was born at Fairview, near Dublin, on Oct. 14th, 1835. The system of apprenticeship being still in vogue when he commenced his professional studies he was bound to Dr. Hatch Power, professor of surgery in the Royal College of Surgeons, Dublin. In 1857 he graduated M.D. (with first honours and gold medal) in the Queen's University. For some years he was engaged in tutorial work and prepared many successful candidates for the medical service of the Crown as well as for graduation. In 1862 he became a Fellow of the College of Surgeons and soon after, in 1867, was elected professor of anatomy and physiology in succession to Professor Jacob, having been appointed in 1864 to the chair of hygiene. He had been surgeon to St. Vincent's Hospital from 1859 as well as to the Children's Hospital. For several years he discharged with conspicuous ability the onerous duties of medical officer of health of Dublin, and many much-needed sanitary reforms owe their initiation to his courage and energy. He was elected President of the Royal College of Surgeons in Ireland in 1879 and it was largely due to his exertions in his year of office that the dental diploma of the College was instituted, while later he took a leading part in the movement which brought about the amalgamation of the Carmichael and Ledwich schools with that of the College. He was the author of many professional works, amongst others "A Manual of Physiology" (three editions), "Lectures on Public Health," and "The Body and its Health," a book for primary schools (six editions). In 1868 he won the Carmichael prize for the best essay on "Medical Education." He delivered the address on public medicine at the Brighton meeting of the British Medical Association in 1886. During the next few years he spent a considerable time at the centres of medical education in France and Germany in the study of skin diseases as well as syphilis and gout.

In 1888 he removed the sphere of his consulting practice to London and was presented with a farewell address by the leading members of the profession in Dublin. In that year he was President of the Dublin branch of the British Medical Association. Dr. Mapother was also a Fellow of the Royal Medical and Chirurgical Society, a member of council of the Medical Society of London, and chairman of the Irish Medical Schools' and Graduates' Association. He was also for some years, 1880–1885, surgeon to the Lords Lieutenant of Ireland.

He married in 1870 Ellen, daughter of the Hon. John Tobin, M.P., of Halifax, Canada, who survives him and has issue one son, Edward Mapother, M.B., B.S. Lond., who has lately entered the medical profession and is at present house physician at University College Hospital, and six daughters, of whom five survive.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced: Dr. Ferdinand Petersen, extraordinary professor of surgery in the University of Kiel, aged 62 years.

derived from primary dry cells. It is most convenient and useful and the fact that it can easily be recharged is not the least recommendation about it. Considering its small size it is remarkably effective. We received a specimen lamp, which came through the post without injury, from Messrs. G. E. Wilson and Co., of 20, Cross-street, Manchester, and the price is 8s. 6*d.*

A COINCIDENCE IN INVENTION.

To the Editor of THE LANCET.

SIR,—In your issue of March 7th a communication is published from Mr. Seymour Stritch of Dublin upon a new pessary. May I venture to call your attention to a communication from me in your columns of Oct. 6th, 1900, p. 1020, upon the same subject? Mr. Stritch's pessary is merely mine in a very modified form; in essential features, ring on hinged stem, it is the same. As a matter of fact, and as the result of experience, I have discarded the "ring" pattern in favour of the "Hodge," and find that in every way it gives satisfaction to both patients and myself. Messrs. Krohne and Sesemann, 37, Duke-street, London, W., have made my instrument in considerable numbers since its first conception, and I am sure they will be pleased to show it at any time to Mr. Stritch—in both "ring" and "Hodge" patterns. I do not for a moment suggest that Mr. Stritch could either have seen my article, or the pessary itself, before offering his communication to your journal.

I am, Sir, yours faithfully,

Woodford Green, Essex, March 10th, 1908. HUGHES R. DAVIES.

"WON'T-LET-GO" CEMENT.

ACCORDING to our examination this is a carefully prepared gelatin cement and a practical trial convinced us of its effective adhesive qualities. It is very clean to use and is contained in a collapsible metal tube. The makers, Messrs. J. E. Morgan, of 63, Ludgate-hill, London, E.C., suggest its use by surgeons and in hospitals on account of its strength and antiseptic properties. We confirmed the presence in it of a pleasant antiseptic oil.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.).

TUESDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (18th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.).

THURSDAY (19th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.)

FRIDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (21st).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.—(*Pathological Section*). 8.30 P.M., Mr. S. G. Shattock: Specimens of the Larvæ of Eristalis Tenax passed by the Bowel. Mr. C. B. Walker: Enlargement of Hen's Comb produced by Injections of Testicle Extract. Dr. L. Barlow: The Relation of Endothelioma to other Forms of New Growth. With papers and demonstrations bearing on the subject by Mr. C. W. Rowntree, Mr. A. Leitch, and Dr. L. Courtauld.

THURSDAY.—(*Dermatological Section*). 5 P.M., Clinical Cases will be shown by Dr. J. H. Sequeira and others.

CHILD STUDY SOCIETY LONDON, Parkes Museum, Margaret-street, W.

THURSDAY.—8 P.M., Dr. F. C. Shrubsall: Anthropometry and Physical Development (illustrated by lantern slides).

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Mr. C. F. Rousselet: Exhibition of Mounted Specimens. Right Hon. Lord Avebury: On Seeds, with Special Reference to British Plants.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN, 11, Chandos street, Cavendish-square, W.

FRIDAY.—5 P.M., Dr. F. Langmead, Dr. P. Weber, Dr. C. Chapman, Dr. G. Carpenter, Dr. P. Parkinson, Mr. S. Stephenson, and others: Cases and Specimens.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 20, Hanover-square, W.

FRIDAY.—8.30 P.M., Mr. A. E. Shipley: The Relation of Entozoa to the Mucous Lining of the Alimentary Canal. Dr. W. T. Prout: (1) The Rôle of Filaria in the Production of Disease; (2) Note on an Unusual Cause of Dysenteric Diarrhœa in the Tropics; (3) exhibit of the Sword of a Sword Fish removed from a man who had been transfixed by it.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MONDAY.—5 P.M., Dr. F. A. Bainbridge: The Pathology of Acid Intoxication.

WEDNESDAY AND FRIDAY.—5 P.M., Mr. M. Greenwood: The Physiological and Pathological Effects which follow Exposure to Compressed Air.

(Arris and Gale Lectures.)

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Dr. H. French: The Influence of Pregnancy on certain Medical Diseases, and the Influence of certain Medical Diseases on Pregnancy. (Goulstonian Lectures.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. C. Fox: Clinique (Skin). 5.15 P.M., Lecture:—Dr. F. M. Sandwith: Bilharziasis.

TUESDAY.—4 P.M., Dr. E. Cautley: Clinique (Medical). 5.15 P.M., Lecture: Mr. F. Eve: Experiences and Observations in the Surgery of some Non-malignant Affections of the Stomach.

WEDNESDAY.—4 P.M., Mr. R. H. J. Swan: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. H. Thursfield: Post-Basal Meningitis.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. L. Guthrie: Precocious Development.

FRIDAY.—4 P.M., Mr. R. Lake: Clinique (Ear).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—12 noon, Lecture:—Dr. Low: Pathological. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Dr. Ball: Diseases of the Tonsils (illustrated by lantern slides).

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12 noon: Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Ball: Diseases of the Tonsils (illustrated by lantern slides).

WEDNESDAY.—10 A.M., Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. K. Scott: Diseases of the Eye. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine.

THURSDAY.—12 noon, Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Hood: Arterio-Sclerosis.

SATURDAY.—10 A.M., Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. K. Scott: Diseases of the Eye. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Cliniques:—10 A.M., Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Throat, Nose, and Ear (Mr. H. W. Carson); X Ray (Dr. A. H. Pirie). 4.30 P.M., Medical In-patient (Dr. A. J. Whiting).

TUESDAY.—Clinique:—10.30 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Surgical Operations (Mr. Carson). Cliniques:—Surgical Out-patient (Mr. Edmunds); Gynæcological (Dr. A. E. Giles).

an assistant in distressed circumstances pointed to the early founding of a benevolent fund. Votes of thanks to the master and wardens of the Apothecaries' Society and to the chairman, treasurer, secretary, local secretaries, and committee of the association concluded the business.

Dr. J. Charlton Briscoe has been elected assistant physician to King's College Hospital.

WATERED MILK.—At Gloucester police court on Feb. 27th the dairyman who had the contract for the supply of milk to the Gloucester Workhouse was fined £15 and costs for supplying milk adulterated with 17 per cent. of water to the inmates of that institution.

LITERARY INTELLIGENCE.—Messrs. Wm. Hodge and Co., Edinburgh and Glasgow, announce for publication on March 19th, as a new volume in their series of Notable Scottish Trials, an account of the "Ardlamont Case," which some 13 years ago was the general topic of conversation all over Britain.

DONATIONS AND BEQUESTS.—The late Mr. James Robert Turle by will bequeathed 100 Hudson's Bay shares of the value of about £7700 and £3000 New South Wales 3 per cent. of the value of about £2570 to the London (Royal Free Hospital) School of Medicine for Women; 100 Hudson's Bay shares and £3000 New Zealand 2½ per cent. to the Metropolitan Convalescent Institution; and £8400 London County Council 3 per cent. to the New Hospital for Women, Euston-road, N.W.

HEALTH AND SANITATION OF ST. VINCENT.—Mr. D. T. Tudor, acting administrator, in his report on the blue-book of the colony for the year 1906–07, just presented to Parliament, states that the estimated population in March, 1907, was 51,009. The births registered in 1906–07 were 1768, as against 1709 in 1905–06. Of these 1018, or 57·57 per cent., were illegitimate. Marriages were 141, a decrease of 55 on the previous year's figures, a decreased total which coincided with the increased percentage of illegitimacy. The total registered deaths were 929, as against 775 in 1905–06, being 18·2 per 1000 of the estimated population, a general rate of mortality which, after taking into account the deplorably high rate of infant mortality, must be regarded as very favourable. The infant mortality (infants under one year, exclusive of stillbirths) reached no less a total than 311, being 33·5 per cent. of the whole. The corresponding figures in 1905–06 were 169, or 21·8 per cent. The causes of death were thus tabulated: general diseases (including syphilis 119, tubercle 65, tetanus 37, and malarial fevers 18), 356; diseases of nervous system, 36; diseases of circulatory system, 25; diseases of respiratory system, 51; diseases of digestive system, 132; parasites, 47; age, 87; stillborn, 104; and other diseases, 91; total, 929. In the villages of the peasantry the ideas and methods in sanitary matters are elementary in the extreme. In the towns things are passable. The rainfall for the year 1906–07 was 104·45 inches. Rain fell on 292 days throughout the year. The mean monthly temperature was 78·3° F.; maximum for the year 90° F. in November; minimum, 63° F. in March.

MARYLEBONE HEALTH SOCIETY.—The second annual meeting of this society was held at the Town Hall, Marylebone-lane, W., on March 9th, Lord Robert Cecil being in the chair. He was supported by a number of residents in the borough. The report shows that satisfactory progress has been made during the year in the matter of "health visiting." As is well known, the work is largely directed to the prevention of infant mortality and the prevention of the spread of tuberculosis, and is effected by the personal visiting of the homes of the poor by ladies who are interested in the cause. It is obvious from the report that to engage the mothers' confidence is an important prelude to their conversion to a better sanitary ideal and this is attempted by a system of "tea-talks" which are less formal than ordinary lectures and are proving successful in their aim. The work is greatly strengthened by the "Infant Consultations" at the St. Marylebone Dispensary, at which 110 infants have attended during the year, of whom only three have died, and the general progress of the others has been good. There are 15 ladies voluntarily visiting the poor dwellings in Marylebone, and it is hoped that more will join them. The society has done equally good work with patients suffering from tuberculosis, visiting many whose condition had not been notified to the medical officer of health and instructing them in their personal hygiene. The committee, recording with regret the resignation of Mr. A. Wynter Blyth both as medical officer of health and chairman of the executive committee, pays a tribute to his invaluable help in the past.

THE MEDICAL OFFICER OF HEALTH OF BRIGHTON.—Dr. Duncan Forbes, medical officer of health of Cambridge, was on March 5th elected by the Brighton town council to succeed Dr. A. Newsholme as medical officer of health of the borough at a salary of £600 per annum. There were in all 37 applicants for the position.

HEREDITY AND MORAL RESPONSIBILITY.—A series of lectures will be delivered at St. Edward's House, 22, Great College-street, Westminster, on Fridays, March 13th, 20th, and 27th, and April 3rd and 10th, at 6 P.M., by the Rev. Father Waggett who is a trained biologist as well as a theologian. The subject of the lectures is Heredity or Natural Inheritance in Relation to Moral Responsibility and the Doctrine of Sin. The lectures are for men only and the question will be discussed from the physiological point of view and also from that of the different religious questions which appear to be involved.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Death Certificates (Charges) Bill.

A BILL designed "to amend the Births, Deaths, and Marriages Act, 1836, for the purpose of reducing the charges for death certificates in certain cases" has been introduced into the House of Commons by MR. GILL. It has been read a first time. The measure has the formal support of MR. SHACKLETON, MR. BELL, MR. THORNE, MR. JAMES HASLAM, MR. WILKIE, MR. BOWERMAN, MR. STEADMAN, MR. BARNES, MR. KELLEY, MR. GEORGE ROBERTS, and MR. WILLIAM WILSON.

Public Health Officers Bill.

SIR WALTER FOSTER'S Bill "to amend the law relating to the qualification and tenure of office of medical officers of health and for other purposes" has been printed. Sir Walter Foster states in the memorandum that the main objects of this Bill are to insure that none but those properly qualified shall be appointed as medical officers of health or sanitary inspectors, and to give all such officers and inspectors similar security in their tenure of office to that enjoyed by Poor-law medical officers and metropolitan medical officers of health. Clause 1 proposes to enact that after Sept. 29th, 1910, no person shall be appointed a medical officer of health unless he is a duly qualified medical practitioner, and unless (a) he is registered on the Medical Register as the holder of a diploma in sanitary science, public health, or State medicine under Section 21 of the Medical Act, 1886; or (b) he has for three consecutive years before the commencement of this Act served as a medical officer of health of a district or combination of districts with a population, according to the last published census, of not less than 50,000; or (c) the Local Government Board consents to his appointment.

It is further proposed that after the same date a person shall not be appointed a sanitary inspector unless (a) he is the holder of a certificate of such body as the Local Government Board may from time to time approve that he has by examination shown himself competent for the office; or (b) he has for three consecutive years before the commencement of this Act served as a sanitary inspector of a district or combination of districts with a population according to the last published census of not less than 20,000; or (c) the Local Government Board consents to his appointment.

As the law stands no qualification is required for a sanitary inspector except in London, and as a general rule a medical officer of health or sanitary inspector is appointed from year to year only and thus has no true security of tenure. Poor-law medical officers and metropolitan officers of health are not appointed for limited periods only, and are removeable only by, or with the consent of, the Local Government Board. Accordingly Clause 2 has been framed to amend the law with regard to the tenure of office. It runs as follows: "(1) A medical officer of health or sanitary inspector shall not hold office nor be appointed for a limited period only, and shall be removeable only subject to an appeal to the Local Government Board. (2) This section shall apply to every medical officer of health or sanitary inspector, whether appointed before or after the commencement of this Act, and notwithstanding any contract to the contrary."

Except in London, urban sanitary authorities have no legal power to appoint more than one sanitary inspector. It is desired to extend the metropolitan powers to all urban sanitary districts. In London the sanitary inspector is so called by law, but outside London the law names

only be obtained by a laborious examination of the District records. I may explain, however, that all accidents due to power machinery and other special causes, about one-third of the total number, are investigated on the spot by the certifying surgeon. The surgeon reports to the inspector who then decides whether a further inquiry on his part is necessary. A vast number of the reported accidents are of a trivial character, and even if an investigation of each were possible it could seldom, from the nature of most of them, result in any preventive measures being taken.

Beri-beri on Merchant Vessels.

Mr. G. J. COOPER asked the President of the Board of Trade whether any scientific inquiry was being made by the Board into the cause of beri-beri; and, if not, whether he would consider the advisability of making a grant either to the Royal Society or the School of Tropical Medicine, to be expended in experimental research to discover the specific organism or toxin causing this disease.—Mr. KEARLEY replied (by written answer): The Board of Trade has been in communication with the Royal College of Physicians of London on the subject of beri-beri on board merchant ships and the matter is now before a special committee of Fellows of the College. On receipt of the committee's report the Board of Trade will consider whether any, and if so, what further steps should be taken.

Mr. COOPER further asked whether, as deficiency of nitrogenous food, overcrowding, and defective sanitation were conditions which, if combined, had been found favourable to the development of beri-beri, he would consider the advisability, when directing inquiries into the deaths from this disease of Chinese or Indian lascars on British ships, that these conditions should be reported upon as well as the adequacy and cost of the food supplied daily.—Mr. KEARLEY answered: Yes, sir; the suggestion made in my honourable friend's question shall be borne in mind.

The Supply of Milk in London.

The London County Council (General Powers) Bill was read a second time.

Mr. COURTHOPE then moved that an instruction should be given to the committee which would deal with the Bill that all clauses dealing with the milk-supply except the model milk clauses should be struck out of the Bill. He said that in making this motion he was acting on behalf of the Central Chamber of Agriculture and other bodies. There must be uniformity of local legislation, and in order to secure that uniformity they must move on the basis of model milk clauses, for the reason that they had already been inserted in a hundred private Acts, including those of all the London boroughs. Some other authorities had other clauses dealing with the subject of milk-supply. Power of inspection outside their own area had been given to local authorities, and it was that jurisdiction outside their own area which had caused great inconvenience to the agricultural community. At first it was thought that the purity of the milk-supply could be secured by enforcing sanitary conditions in the cowsheds and dairies. However, the powers under the Dairies, Cowsheds, and Milkshops Order of 1899 had not been found to be sufficient. This Bill sought to place on the farmer the whole responsibility for the state of the milk on its arrival at the place to which it was consigned. It would be said on behalf of the County Council that the impurity took the form of cow-dung and for that the agriculturists were responsible, but tobacco pipes, tobacco, and tea leaves were also found in the milk. The milk churns were often left open at the London termini, where the milk became polluted, and where there was a good deal of thieving of the milk and consequent adulteration. Agriculturists reasonably objected to being burdened with the responsibility for these things. The railway companies had refused to accept any responsibility. The agricultural community had no wish to avoid inspection. The dairyman was already responsible to the local authority in his area and if this Bill were passed he would be made responsible to the London County Council. He admitted that the position of London, into which 50,000,000 or 60,000,000 gallons of milk were brought every year, was unique. However, the President of the Local Government Board had promised legislation on the subject this year and there was therefore all the more reason for resisting piecemeal legislation now.

Mr. HICKS-BEACH seconded the motion.

Mr. GUINNESS said that the London County Council, being unable to obtain an assurance from the President of the Local Government Board that he would introduce a general measure dealing with this question, had felt that it was necessary to propose an extension of the model clauses. If the right honourable gentleman would give an assurance that he would introduce legislation which would insure a supply of pure milk and would also take into consideration the special position of London, the County Council would be relieved of the necessity of proposing special legislation. The County Council held that the model clauses did not go far enough. It was not sufficient to check the supply of tuberculous milk. They wanted also to keep out dirty milk. They approved of the machinery of the model clauses but sought to extend their application. In order to insure a cheap supply the Council was anxious not to throw any undue burden on the local authorities and therefore they had kept the whole power of inspection in the hands of the County Council. They did not propose to take any inquisitorial powers and they felt certain that no clean farmer would be penalised in the least by their clauses. A large portion of the population of London had to depend upon small shops and under present conditions that supply was very insanitary. The state of affairs now existing in London was very dangerous. In Finsbury it was found that 32 per cent. of the samples of milk which had been examined contained pus and 40 per cent. contained dirt. Mr. A. E. Harris, medical officer of health of Islington, last year examined the contents of 34 successive churns of milk at Finsbury Park station and found that no fewer than 33 contained excremental matter. Under present conditions it was quite impossible to discover where contaminated milk came from and so the farmer got off with impunity. It was no use, he submitted, that the metropolitan borough councils should be enabled to proceed against the retailers of milk in London unless some authority—and the London County Council seemed to be the only possible one—was enabled to go to the railway stations and find out what milk was dangerous before it was distributed. The trouble of this dirty milk arose from the fact that in a large number of districts the Dairies, Cowsheds, and Milkshops Orders were not in force. No fewer than 324 sanitary authorities had made no regulations and in other cases no enforcement was insisted upon. The reports of medical officers of health in different counties showed the dangerous condition of things which existed and the filthy and revolting conditions of the cowsheds in many places. A number of the sanitary authorities from whose districts milk was sent to London did not seem to care how many people in the metropolis had their health affected by a poisonous supply. The infantile mortality in London, he contended, was fostered by a contaminated milk-supply, and in the interests of a sanitary milk-supply it ought to be possible for the local authorities in London to step in and to take the place of those sanitary authorities in the country who neglected their duties.

Mr. BURNS (the President of the Local Government Board) said that in addition to the London County Council Bill two other Bills (the Widnes Corporation Bill and the Blackburn Corporation Bill) dealt more or less with the same subject in a similar way. As they were down on the notice paper for consideration that evening he would express the views of the Government upon all three together. The Government took no exception to the instruction moved by the honourable Member for Rye (Mr. Courthope) although it did not identify itself with all the objects and motives which might have influenced the honourable Member and the interests on whose behalf he acted. The time had come when they ought to have a larger, better, and cleaner milk-supply, especially in the interests of the children in large towns. He accordingly intended to bring in a general Bill this session dealing with the milk-supply of the country. The question had become a national one. He believed that the public could be protected without handicapping the farmer or harassing the dairyman and that the interests of the progressive farmer and the clean and enterprising dairyman should lead them to coöperate in insuring for their trade cleanly and scientific conditions. The Bill which he proposed to bring in would seek to secure cleanliness, purity, and reliability in the milk-supply and to remove the evils of overlapping jurisdiction and would deal with the question of compensation in certain cases, with the conditions of valuation, the price to be paid, and a number of other matters. He believed that there was an increasing recognition of the value of milk as an article of diet both for young and old, but he feared that the speech of the honourable Member for Bury St. Edmunds (Mr. Guinness) was rather of a character to make people say with Eccles in *Caste*, "Milk, milk; I would rather have a drop of cold refreshing gin." The Government would take into consideration the need of London for exceptional treatment on account of its exceptional character and size. The milk-supply of London could not be satisfactorily controlled unless the central body had greater control than it now had, not only over milk but over a number of things. He would assure the Members for Blackburn and Widnes and the Members who represented the London County Council that nearly all that each of them sought would be embodied in the Government Bill along with other matters which they had not mentioned. He hoped the motion of the Member for Rye (Mr. Courthope) would be carried without a division.

Mr. HARWOOD-BANNER was afraid that the right honourable gentleman had squared the agricultural interests to the prejudice of the interests of localities.

Mr. BURNS: You will not say so when you see the Bill.

The motion for the instruction was agreed to without a division.

When the Blackburn and Widnes Corporation Bills had been read a second time instructions to the committee were also agreed to striking out all clauses dealing with milk-supply other than the model milk clauses.

MONDAY, MARCH 9TH.

Phosphorus in Matches.

Mr. T. P. O'CONNOR asked the Secretary of State for the Home Department whether, in view of the deaths from poisoning of women and children from consuming phosphorus taken from match heads, he would state whether any record of these cases was kept; and, if so, how many deaths had occurred during the year 1907 from this cause.—Mr. GLADSTONE answered: The deaths returned by coroners' juries as resulting from poisoning by phosphorus from matches are shown in the Registrar-General's annual reports. The figures for 1907 have not yet been ascertained. The Registrar-General informs me that in 1905 six deaths were attributed to poisoning from phosphorus matches, five of the victims being children under three years of age and one a girl of 12 years.

Mr. T. P. O'CONNOR further asked whether the right honourable gentleman had any information to the effect that the sale of phosphorus matches was strictly prohibited in Norway and Sweden but that the manufacture in those countries was still permitted for export to this country.—Mr. GLADSTONE replied: My information is that the sale of lucifer matches containing white or yellow phosphorus is forbidden in the countries mentioned, but not the manufacture for export.

Legislation in regard to Milk.

Mr. WATT asked the President of the Local Government Board whether in the forthcoming legislation dealing with milk-supplies the Bill will include Scotland.—Mr. BURNS answered: This point has not at present been settled. It will be a matter for the Secretary for Scotland.

Mr. WATT asked the Secretary for Scotland whether he would introduce some system of inspection which would enable the large towns of Scotland to inspect the farms from which their milk-supplies came.—Mr. SINCLAIR said, in reply: I cannot give my honourable friend any assurance at present as to the attitude of the Government, but he is aware that a Bill dealing with this question has been introduced by a private member and it is hoped that some opportunity for discussion may arise which may help to mature it.

Vaccination of Borough Employees in Hampstead.

Mr. BOWERMAN asked the President of the Local Government Board whether he could say how many of the employees of the Hampstead borough council had been vaccinated within the past six years; whether he was aware that the fee charged for each employee was 5s., and that they were vaccinated by a doctor who was, and had been, a member of the council at the time; and whether, seeing that the council employed a member of its own body to do this work, he proposed to take any, and what, action in the matter.—Mr. BURNS replied: I am informed that the borough council have never made any condition as to the vaccination of their employees and have no record of the number vaccinated during the last six years. I find, however, that during the last epidemic of small-pox in 1901 one of the employees who had not been vaccinated died from the disease, and hence three of the committees of the borough council thought it desirable that the muscle and appears to play an active part in metabolism; possibly it forms a stage in the transformation of sugar into fat or the production of sugar from proteid. The calorie value of lactic acid is almost equal to that of sugar and it may be expected therefore that its oxidation will occur in those tissues—namely, the muscles, which are the chief source of body energy. Hopkins and Fletcher have found that such is the case and that in the presence of oxygen frog's muscle can oxidise lactic acid. This mechanism is probably of great physiological importance, although during excessive muscular activity it is inadequate to deal with the large amounts of lactic acid formed and the acid appears in the urine. Several grammes of lactic acid have been obtained from the urine of patients shortly after an epileptic fit. And it seems almost certain that the occurrence of lactic acid noticed by Zweifel in eclampsia was due to the eclamptic convulsions, since he has not proved the presence of lactic acid in the urine before the onset of the convulsions. The observation of Longridge that in eclampsia the alkalinity of the blood is diminished does not support Zweifel's view that eclampsia is an acid intoxication caused by lactic acid, for Cohnstein has found that severe muscular exercise is capable of lowering the alkalinity of the blood. Further, much larger amounts of lactic acid than those found in eclampsia by Zweifel have been injected into the blood streams of animals without causing toxic symptoms. Finally, it may be pointed out that even in carbon monoxide and prussic acid poisoning the muscles as well as the liver are damaged and the appearance of lactic acid is due mainly to interference with the oxidation of lactic acid in the muscles.

These facts lead, I think, to the conclusion that lactic acid is never the cause of acid intoxication in man and that its appearance in the urine is either the result of excessive production by the muscles or is secondary to the failure of the liver to convert ammonia into urea; its occurrence is not due to deficient oxidation of lactic acid by the liver.

THE ACETONE BODIES.

Lactic acid is known to be normally formed in metabolism, but there has been much discussion as to whether this also holds good for the acetone bodies. There are many facts which render it highly probable that β-oxybutyric acid is a normal metabolic product. Knoop's experiments on the oxidation of aromatic compounds of the lower fatty acids in the body show that oxidation can occur in the β position; and Dakin has found that β-oxybutyric acid is probably formed when ammonium butyrate is oxidised *in vitro*. It is known also, from the observations of Schwarz and Waldvogel, that the tissues are able fully to oxidise considerable amounts of β-oxybutyric acid given by the mouth. On the other hand, diacetic acid has never been found in normal urine; traces of an iodoform-yielding substance have frequently been obtained in normal urine, but the iodoform reaction is yielded by so many substances other than acetone that it is doubtful whether acetone occurs normally in urine. The tissues seem unable to burn up acetone when given by the mouth, since the bulk of it can be recovered from the breath and urine, and it seems improbable that acetone is formed in normal metabolism. The fact, noted by Satta, that the iodoform-yielding substance in normal urine is uninfluenced by carbohydrate food points to this conclusion.

Although the chemical relationship of these bodies is very close, the failure to obtain diacetic acid from β-oxybutyric acid *in vitro* had raised doubts as to whether diacetic acid and acetone were really derived in the body from β oxybutyric acid. Dakin has shown, however, that diacetic acid and acetone are readily obtained by the oxidation of ammonium butyrate with hydrogen peroxide.

The view that the acetone bodies arise from fat has been largely developed by Rosenfeld, Waldvogel, Hirschfeld, and Geelmuyden. Waldvogel showed that a meal of proteid during a period of starvation lessened the output of acetone bodies; Geelmuyden found that the addition of large amounts of fat to the diet increased the acetonuria; and, finally, Rosenfeld observed that the acetone bodies appeared in the urine of healthy men on a full diet of proteid and fat if carbohydrates were withheld. In man the appearance of the acetone bodies in the urine is usually the result either of a deficiency of carbohydrate food or, as in diabetes, of inability of the tissues to utilise carbohydrates, and, according to Hirschfeld and Geelmuyden, very small amounts of carbohydrate (50 to 100 grammes) suffice to abolish the acetonuria of starvation.

There seems to be no doubt that when carbohydrate is withheld, and still more in starvation, the consumption of fats is excessive, and the view has been put forward that the tissues, unequal to the strain thus put upon them, fail to oxidise the fats completely and that β-oxybutyric acid passes into the blood and urine. If this view is correct, a diet of fat only should still further increase the strain on the tissues and should largely increase the excretion of β oxybutyric acid; Geelmuyden found that such was the case in a man who lived for several days on large quantities of oil and a little vinegar. On the other hand, many observers have found that the addition of fat in starvation had little or no influence upon the acetonuria. In the careful experiments of Joslin on a healthy starving man 100 grammes of butyric, stearic, or palmitic acid did not increase the output of acetone bodies, although examination of the fæces showed that the bulk of the fatty acid was absorbed. He also quotes the following figures from Rosenfeld:—

Total Acetone Bodies in Urine.

Day.	Starvation.	190 grammes of butter daily.	800 grammes of meat daily.
1	0·09 grm.	0·08	0·016
2	0·3 "	0·23	0·012

In other cases the increased output of acetone bodies was trifling in comparison with the additional intake of fat, a result in accordance with von Noorden's dictum that fat given to a starving man does not increase the total consumption of fat, but that the fat of the food is used instead of the body fat. Admitting then that the acetone bodies are derived from fat, and that in starvation the consumption of fat is increased, the inconstancy of the results obtained on a diet of fat indicates that the tissues of a healthy man can deal with large quantities of fat, and that it may not be safe to assume that the acidosis of starvation is the direct result of the excessive consumption of fat.

The facts, moreover, are capable of a totally different interpretation. The acidosis of starvation can be abolished by the administration of quite small amounts of carbohydrate, amounts so small that the energy which they supply to the body is slight and cannot greatly lessen the consumption of fat. In may be that in starvation acidosis occurs not because the consumption of fat is excessive, but because carbohydrate is absent, and the addition of carbohydrate may abolish acidosis not only by supplying energy to the body but also by modifying the metabolism of the cells. We know very little of the complex mechanism of metabolism, and it is quite conceivable that the presence of carbohydrate or its products is essential to the carrying out by the cell of some of its oxidative processes, including the complete oxidation of fat. And there is some evidence that the metabolism of fat may be made to follow its normal course by the administration of substances other than carbohydrate. Satta has studied the effect of a number of substances which lessen acidosis, and which he calls "anti-ketoplastic." These bodies include tartaric and citric acid. He found that 40 grammes of citric acid given daily greatly lessened the acidosis of starvation. The results of Baer and Blum are more conclusive. They examined the effect of glutaric and the homologous dicarboxy acids upon the acidosis of phloridzin glycosuria, and some of their results are shown in the following table:—

Day.	Total nitrogen.	Sugar.	Acetone.	β-oxybutyric acid.
1	5·9	14·8	209 mgr.	1·49 grm.
2	6·2	18·0	465 "	2·29 "
3*	3·1	7·5	49 "	0·18 "
1	8·2	13	288 mgr.	1·78 grm.
2	8·0	11	323 "	2·73 "
3†	1·5	< 1	106 "	0 "

† 7 grm. adipic acid.

† 10 grm. glutaric acid.

They consider that the retention in the body of sugar, nitrogen, and acetone bodies can be excluded and that glutaric and other homologous acids modify the nitrogenous

Lowestoft Hospital.—House Surgeon, unmarried. Salary at rate of £80 per annum, with board, lodging, and washing.

Macclesfield General Infirmary.—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.

Maidstone, West Kent General Hospital.—Assistant House Surgeon, unmarried. Salary £80, with board, lodging, and washing.

Manchester, University of.—Senior Demonstrator in Physiology. Salary £150, rising to £200 per annum.

Merthyr Tydfil, Borough of.—Medical Inspector of School Children. Salary £200, advancing to £300.

Middlesbrough, North Riding Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, and washing.

Mountain Ash Urban District Education Committee.—School Medical Inspector. Salary £250 per annum.

National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, W.C.—Registrar. Salary £150 per annum.

Newcastle-upon-Tyne Dispensary.—Resident Medical Officer. Salary £250, with residence.

New Hospital for Women, Euston-road.—Three Senior Assistants (females).

Plymouth, South Devon and East Cornwall Hospital.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

Rotherham Hospital and Dispensary.—Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

Royal Free Hospital, Gray's Inn-road, W.C.—Senior Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Also Resident House Surgeon for six months. Board, &c., provided.

Royal National Orthopædic Hospital, Great Portland-street, W.—House Surgeon, unmarried. Salary £250 per annum.

Royal Navy, Medical Department.—Examination for not less than 15 Commissions.

St. Mary's Hospital, Paddington, W.—Medical Officer in Charge of the X Ray Department. Salary £100 per annum.

Southampton, Royal South Hants and Southampton Hospital.—House Surgeon, also House Physician. Salaries £100 per annum respectively, with rooms, board, and washing.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Junior House Surgeon. Salary £90 per annum, with residence, board, and washing.

Stafford, Staffordshire General Infirmary.—Assistant House Surgeon. Salary £52 per annum, with board, residence, and laundry.

Stockton-on-Tees Education Committee.—Assistant to the Medical Inspector of School Children. Salary £200 per annum.

Taunton and Somerset Hospital, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

Torquay Education Authority.—Assistant School Medical Officer. Salary £150 per annum, rising to £210.

Torquay, Torbay Hospital.—House Surgeon. Salary £100 per annum, with residence, board, and washing.

West Bromwich District Hospital.—Resident Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing.

West London Hospital and Post-Graduate College, Hammersmith-road, W.—Clinical Assistants.

Westminster General Dispensary.—Resident Medical Officer. Salary at rate of £120 per annum, with rooms, gas, coal, and attendance.

Worcestershire Education Committee.—Inspector of School Children and Midwives. Salary £400 per annum, with travelling expenses. Also Two Assistant Inspectors. Salary £175 per annum, with travelling expenses.

Worthing, Borough of, and Rural District of East Preston, Combined Sanitary District.—Medical Officer of Health. Salary £500 per annum.

The *Chief Inspector of Factories*, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Killane, in the county of Wexford; at Drumcollogher, in the county of Limerick; at Kingscliffe in the county of Northampton; at Ederney, in the county of Fermanagh; at Castletown, in the county of Caithness; at Carrickmacross, in the county of Monaghan; at Haddenham, in the county of Cambridge; and at Week St. Mary, in the county of Cornwall.

Births, Marriages, and Deaths.

BIRTHS.

Atkinson.—On March 1st, at Church-street, Saffron Walden, the wife of Dr. H. W. Atkinson, of a daughter.

Butler.—On March 7th, at Romagna House, Otley, Yorkshire, the wife of Somerset E. M. Butler, L.R.C.P. & S. Irel., of a daughter.

Hemming.—On March 6th, at Bishop's Waltham, Hants, the wife of Claude P. Hemming, M.R.C.S., L.S.A., of a daughter.

Hobbs.—On March 6th, at Burke House, Beaconsfield, the wife of Geoffrey Charlstrom Hobbs, L.R.C.P., L.S.A., of a daughter.

DEATHS.

Bickersteth.—On March 7th, at 2 Rodney-street, Liverpool, Edward Robert Bickersteth, F.R.C.S., in his 80th year.

Dowson.—On March 8th, at the residence of her son, Dry Street Farm, Langdon Hills, Essex, Elizabeth Martha, widow of the late Edward Dowson, M.D., of 117, Park-street, Grosvenor-square, aged 75.

Granger.—At 2, Grosvenor-terrace, Glasgow, on March 8th, Maria Sophia Carmichael, widow of the late Dr. John Ross Granger, in her 60th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PUBLIC TELEPHONE CALL OFFICE AS A FACTOR IN THE SPREAD OF DISEASE.

Under the above heading we published an annotation in our issue of July 27th, 1907, p. 240, drawing attention to the dangers which might arise from dirty telephone apparatus and call boxes. A correspondent has sent us a letter containing a number of concrete instances in which he alleges that he has found dirty instruments. We do not publish the full addresses but we shall be happy to send them to the National Telephone Company. Our correspondent says:—

> Being obliged to make continual use of public call offices, the writer has felt on several occasions that the dirty condition of the apparatus made its use extremely risky. A few instances of unsatisfactory conditions may serve as examples. 1. Call box, E.C.: Instrument very dirty; box apparently never swept out judging by the collection of rubbish in it, including about sixpence in coppers, which could be seen on striking a match. 2. Call office, —— station: Apparatus very dirty; mouthpieces dripping condensation from breath of previous users; smell disgusting. 3. Call office at shop, ——, Kent: Apparatus dirty and dripping condensation as above. 4. Call offices, —— station, platform: Apparatus dirty; smell so disgusting that the writer went elsewhere. 5. Call office, —— road, N.E.: Instrument dirty; smell disgusting. 6. Call box, —— station: As above. On the occasions when the writer has used call offices at the following places the condition of the apparatus was unsatisfactory, the vulcanite mouthpieces frequently containing débris with a more or less bad odour: Chatham, Deal, Croydon, Harlesden, Kilburn, Lewisham, Catford, Beckenham, Bromley (Kent), Southampton, Bournemouth, and London, W., London, S.W., and London, E.C., many cases. Only two instances are in mind where an attempt was made to keep the apparatus really clean and to disinfect the call box, this out of a series of several thousand calls. A notice with regard to this unsatisfactory state of affairs in your valuable paper might lead to an improvement.

THE PRESCRIBING OPTICIAN.

A correspondent has forwarded to us a little pamphlet entitled "A Few Facts You Ought to Know." This is issued by S. Leighton and Son, spectacle specialists, New Market Entrance, Lancaster. Messrs. Leighton and Son commence by saying: "It is a curious fact that whilst most people will call in a doctor when they experience the least pain or ache, or consult a lawyer when in doubt on a trivial legal matter, they will defer seeking the services of an optician until the intensity of the eye strain becomes unbearable." From this sentence it is evident that Messrs. Leighton consider that an optician is the proper person to consult for eye strain. The extent of Messrs. Leighton's knowledge of ophthalmic optics may be gauged from the following sentence: "Long sight is that condition of vision when the rays come to a focus in front of the retina." After this all the flummery about the ophthalmometer, the ophthalmoscope, and the "retinoscope" may be discounted, but no doubt many persons into whose hands Messrs. Leighton's pamphlet may fall will believe that they are competent to treat errors of refraction.

LAY MEDICINE.

We extract the following gem from our contemporary the *Star* of March 10th. The credulity of many persons concerning their own or other people's health is amazing and the confusion between sarsaparilla and sal prunella is delightful.

> A Sure Cure for Quinsey when at the Point of Breaking.—First suck a piece of sarsaparilla ball, obtainable at any chemist's. Then take a pound of ordinary currants and make two poultices. Place one on the throat as hot as possible, and when that is cold put on the other. This I know is a sure cure for quinsey, as I have tried it myself.

THE THOMPSON POCKET ELECTRIC LAMP.

We have not seen a more compact or smaller secondary battery than that which is contained in this pocket electric lamp. Our measurements of the cell were as follows: height 2¾ inches, width 1¾ inches, and depth ¾ inch. The weight of the complete apparatus is a little over half a pound (8½ ounces). The cell contains the usual lead plates immersed in dilute sulphuric acid. The cell is further packed with an acid-proof absorbent material resembling glass wool so that the risk of spilling the acid is reduced to a minimum, and, in fact, the cell may be inverted without loss of acid. This alone is a convenient feature of the lamp. A maximum charge gives from four to six hours' continuous light. The accumulators may be easily recharged from the main continuous current, a 5-candle-power lamp being used as a resistance on the 100-volt circuit and an 8-candle lamp on the 200-volt circuit. The light is remarkably bright and steady. Altogether the lamp is a decided improvement on the ordinary miniature searchlight-lamps in which the energy is consumed by diabetic patients, it seems quite possible that the intake of proteids yielding much leucin may appreciably influence the degree of acidosis, and experiments carried out from this standpoint might be of considerable value in showing which proteids are the most suitable in diabetes. I have already referred to the work of Satta and of Baer and Blum on the influence of citric and glutaric acids in lessening acidosis. These substances should be of extreme value in diabetes in which carbohydrate is not available, and through the kindness of Dr. Norman Moore, Dr. Hurtley and I have had the opportunity of studying the effect of citric and glutaric acids upon the output of acetone bodies in a diabetic patient. The results of giving 20 grammes of citric acid daily for a week are shown in the following table :—

Day.	β-oxybutyric acid.	Acetone and diacetic acid.	Total estimation as β-oxybutyric acid.
1	10·83 grm.	3·19 grm.	15·38
2	5·88 "	2·43 "	9·35
4	1·64 "	0·93 "	2 96
6	2·03 "	1·19 "	3 73 *
8	4·58 "	1·02 "	6 03
10	4·51 "	1·61 "	6·81
12	7·13 "	·59 "	10·83

* 20 grammes citric acid daily.

Similar effects were obtained by the use of glutaric acid, and while not laying too much stress upon the results of one or two experiments, these figures seem suggestive; if they can be uniformly obtained, the employment of citric acid and other substances may render the treatment of acidosis much more hopeful than has hitherto been the case and may delay the onset of coma.

It is well known that in starvation even a severe acidosis is consistent with fair general health, and it is not uncommon for a diabetic patient to excrete for months large quantities of β-oxybutyric acid without showing any symptoms of poisoning. But it does not follow, therefore, that a prolonged acidosis is not harmful to the tissues, although their appearance may be long delayed; the grave metabolic disturbances which usher in diabetic coma probably represent the final defeat of the tissues in their struggle to eliminate the acids, which they produce, and to preserve intact their normal metabolism and chemical constitution. Our knowledge of the pathology of diabetic coma is very limited, but apart from the clinical symptoms definite changes occur in the blood and urine, and I may briefly refer to them before proceeding to discuss their possible explanation. The onset of coma is usually preceded for a day or two and accompanied by a fall in the output of the acetone bodies, the excretion of β-oxybutyric acid may sink from 15 grammes or more to as little as one gramme, and the acetone and diacetic acid may be either absent or present only in traces. Some estimations by Folin of the total amount of acetone in the urine before and during coma show this very clearly and confirm the qualitative observations of West, Wolpe, and others. The large excretion of β-oxybutyric acid in coma observed by Magnus Levy is only observed after the administration of sodium carbonate and does not seem to occur when coma takes its normal course.

The decreased excretion of acetone in the breath also indicates that the production of acetone bodies is actually lessened and that the kidneys are not unable to carry out their functions. The fall in the output of sugar and nitrogen, the fall of body temperature, and the lessened intake of oxygen all point to a decline in the total metabolism. Equally characteristic features of coma are the diminished alkalinity of the blood and its diminished content of carbonic acid.

From these facts Stadelmann, and later Magnus Levy, drew the conclusion that the organic acids produced in diabetes combine with so much alkali in the blood that not enough is left to take up the carbonic acid from the tissues; carbonic acid, therefore, accumulates in the tissues and finally poisons them. Diabetic coma is, in fact, due to poisoning by carbonic acid. But Beddard, Pembrey, and Spriggs found that even in cases in which the alkalinity and CO_2 content of the blood were very low, the blood when shed was able to take up a normal amount of carbonic acid, and they concluded that the capacity of the blood in diabetic coma to take up carbonic acid is not impaired. Again, if Stadelmann's view is correct the tension of carbonic acid in the tissues should be very high and the CO_2 tension of the saliva or urine should also be high, since the tension of carbonic acid in these fluids closely approximates to that of the secreting tissue cells; in point of fact, Beddard, Pembrey, and Spriggs found that the CO_2 tension of the urine was not raised. In the face of their observations it is very difficult to believe that the theory of the overloading of the tissues with carbonic acid offers an adequate explanation of diabetic coma.

A fundamental objection to this view is that the primary morbid alteration is assumed to occur in the blood instead of the tissues, whereas the composition of the blood is ultimately regulated by the tissue cells and the causation of diabetic coma lies almost certainly in their abnormal metabolism. It is not easy, however, to form a clear conception of the way in which the organic acids produced by the tissues eventually disturb their metabolism. Acid intoxication, in the strict sense of the term—that is, poisoning by hydrogen ions—never occurs, since the tissues never lose their alkaline reaction; the term is justifiable, however, if it is used to describe the metabolic disturbances resulting from the abnormal production of acids in the body or from the administration of mineral acids accompanied by a fall in the alkalinity of the blood and tissues. The tissues are very sensitive to even a slight diminution in their alkalinity, and the acute intoxication produced by mineral acids is believed to be due to a fall in the alkalinity of the blood and tissues or, in other words, to a diminution in the concentration of hydroxyl ions relative to the hydrogen ions; this has been proved to occur as far as the blood is concerned. The close similarity between the symptoms of acute acid intoxication in animals and those of diabetic coma naturally suggests that the latter is also an acid intoxication. And Magnus Levy considers that the amount of β-oxybutyric acid present in the blood and tissues in diabetic coma is more than equivalent to the quantity of mineral acid required to produce symptoms of acid intoxication in animals; his calculations were based upon the lessened alkalinity of the blood and tissues in coma.

Moore has shown that the blood, in virtue of its phosphates and carbonate, can take up large amounts of acid or alkali without appreciable alteration in its reaction; this is effected by alterations in the relative amounts of mono- and di-sodium phosphate and of sodium carbonate. It is possible that as long as the blood can take up the acids produced by the tissues no symptoms of intoxication arise, but that if the protective mechanism provided by the phosphates becomes inadequate and the alkalinity of the blood falls, the tissues can no longer get rid of the acids which they produce and their accumulation in the cells brings metabolism to an abrupt end.

On the other hand, Benedikt, making use of physical methods, has shown that in conditions other than diabetes the alkalinity of the blood may be lower than that ever observed in diabetic coma, without the appearance of symptoms of intoxication. These results constitute a serious objection to the view that diabetic coma is an acid intoxication. We do not know, however, that the condition of the tissues can be inferred from the alkalinity of the blood. It may be that the tissues take up alkali from the blood to combine with the acids which they produce, and that the decreased alkalinity of the blood is a secondary phenomena. Possibly, also, too much stress has been laid upon the analogy between diabetic coma and experimental acid-intoxication. Acute mineral acid intoxication lasts only a few hours or days, and the conditions may be very different in diabetes, in which a prolonged acidosis lasting for months or even years ultimately ends in coma. In the latter condition there is a continuous drain upon the alkalies and alkaline earths of the body, since the formation of ammonia is insufficient to combine with all the acid excreted. In the acidosis of diabetes the excretion in the urine of calcium and magnesium, probably also of sodium and potassium, is abnormally large. Part of the calcium is derived from the bones, but the observations of Gottein show that the muscles also probably lose calcium. He found that animals fed on a diet rich in calcium stored it up in the bones and muscles, whereas on a diet poor in calcium both these tissues yielded calcium to the urine. There is also evidence

WEDNESDAY.—Cliniques:—2.30 P.M., Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1907, which was completed with the issue of Dec. 28th, were given in THE LANCET of Jan. 4th, 1908.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

ON

TUBERCULOSIS OF THE KIDNEY,

AND

MALIGNANT DISEASE OF THE CÆCUM.

Delivered before the Medical Society of London on Feb. 3rd and 17th, and March 2nd, 1908,

BY CHARTERS J. SYMONDS, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO, AND JOINT LECTURER ON SURGERY AT, GUY'S HOSPITAL.

LECTURE II.[1]

Delivered on Feb. 17th.

TUBERCULOSIS OF THE KIDNEY (*continued*).

MR. PRESIDENT AND GENTLEMEN,—In the first lecture I placed before you cases illustrating the early signs of renal tuberculosis and showed the condition of the kidney when removed. Except in one there was no enlargement to be felt, and in the instance where this occurred it appeared somewhat suddenly as a final symptom (Case 4).

Before offering some comments upon the points raised by these cases a word must be said of that form of renal tubercle which gives rise to a tumour. The large, moveable, painless, tuberculous kidney is too well known to need any but a passing reference. The cases are fairly common and those that have come under my notice have all given a history of attacks of pain extending over one to three years. In a typical case operated upon in 1902 and quite well in 1908 there had been frequent micturition in the early stages and then repeated attacks of pain. As the tumour enlarged the vesical symptoms ceased. The tumour could be seen moving on respiration, was lobulated, painless, and resembled a hydronephrosis. There were very little pus and albumin in the urine and no increase of urine or pus after an attack. The general health of these patients is on the whole good and they are able to work. These cases resemble hydro- or pyonephrosis in the length of the history, the character of the pain, the moveable and lobulated character of the tumour. I call attention to this, not as an early form of renal tuberculosis but as one where the diagnosis can now in all probability be settled by an examination of the urine.

Before considering the question of treatment I would call attention to certain of the early symptoms. Amongst these renal colic is perhaps the most interesting of all the initial signs of renal tubercle. The exact resemblance to that produced by a calculus cannot be better exemplified than in Case 2. Here was a man of 46 years, though not up to hard work yet looking in good health, seized with severe renal colic. And not only did the three attacks thus closely resemble calculous disease but the likeness was made still closer by the vesical irritation which followed. In Case 1, a young lady, aged 20 years, the long interval between the attacks—one year—points once more to the necessity of careful and routine examination of the urine if we are to discover and treat tubercle early. When renal colic occurs it would seem to indicate that excavation has taken place, whether in one small focus, as in Case 1, or in several, as in Case 2. I mean it suggests more than miliary tubercle and would support the decision to operate. This symptom was absent in Case 3, where the ureter was affected, so that this latter condition may exist without spasmodic pain. Regarding the value of renal colic as an indication of the stage and distribution of tuberculosis, it must have occurred at a very early stage in Case 1, for when the kidney was removed two years later the original focus was small. On the other hand, in Case 2, where the first attack occurred four months before removal, the specimen shows that the disease must have been in existence for a long time—two years or more. The curious abdominal attacks preceding by some two years the vesical symptoms in Case 4 must be grouped under this head.

Albuminuria, one of the early signs of renal tuberculosis, has perhaps not attracted sufficient attention. The association with vesical irritability especially should lead at once to an examination of the urine for bacilli, and again when the amount of albumin is more than can be accounted for by the pus. In Case 4 the cystoscope pronounced the kidney and ureter free from disease but the large amount of albumin led us to fear bilateral renal infection. That it came from one side was proved by its disappearance after nephrectomy. The amount of albumin does not appear to bear any uniform relation to the extent of disease, nor apparently to the form which it takes. Thus in Case 1, with the tuberculous process limited to the lower pole, the albumin was at times abundant. In Case 3, with far more extensive disease but without excavation, the albumin was never excessive, though always more than could be explained by the pus. This is the main point as regards albumin—the proportion to the pus. The contrast was most marked in Case 4, where the pelvis of the kidney was obliterated and the tuberculous foci were shut off from the ureter. In Case 2, with destruction of the lower third of the kidney and recent miliary tubercle, the albumin was never abundant. The fact that miliary tubercle is a painless condition, and that extensive destruction may take place without pain, intensifies the importance of a bacteriological examination of the urine when albumin is present without a general cause being found.

Vesical and urethral irritability without implication of the bladder were in one case (Case 3) the only symptoms up to the time of operation. There was just a suspicion of right renal infection, but only with the aid of the cystoscope was accurate diagnosis possible. This symptom in another case (5) had existed for more than a year, and at one time was thought to be a reflex effect of hæmorrhoids, which were in consequence removed, but without benefit. It was sufficient to limit this patient's activities and it will be remembered that the next symptom was hyperpyrexia without any localising sign. Perhaps the cystoscope might have indicated the kidney affected and saved the laparotomy, but the case occurred in 1897 before I was personally acquainted with the value of this method of examination.

As might be expected when the bladder is involved, the vesical irritability is more pronounced, and so no doubt it is, but, on the other hand, as shown by Case 4, the vesical irritation may be quite moderate where marked tuberculosis exists. In more than one instance of renal tubercle, without vesical disease, it was this symptom that alone compelled attention. That the bladder is tolerant of tuberculous pus is shown by several cases. In some the infective material must have entered the bladder for two years without causing irritation; in others probably for a longer period; while in other cases I have seen quantities of almost pure pus passed with little vesical irritation. This point is worth noting in view of the possibility of this complication being unduly urged as an argument for immediate operation.

At what period in the course of renal tuberculosis does vesical irritation arise and to what is this symptom due? An examination of the specimens in the light of the history of these cases shows that renal tuberculosis may reach an advanced stage without causing vesical symptoms. For example, in Case 2, and probably also in Case 3, the renal condition had existed some time before the urethral pain arose. It would appear, then, that this symptom, when persistent, indicates advanced disease of the kidney. Again, it is to be noted that in all the cases operated upon the ureter was involved and that where the cystoscope was employed the lips of the orifice were everted and swollen and in one studded with tubercles. It is probable that the persistent irritation indicates extensive ureteric infection. That the mere fact of ureteric infection is in itself not the cause is shown by the disappearance of the pain after nephrectomy. The passage of the urine down a narrowed channel appears to be the explanation of this pain. Evidently a small plug of mucus will be sufficient to cause severe colic, as it did in Case 2. The above reasoning is sufficient to show the importance of this symptom, as indicating, when persistent, advanced disease and pointing to the necessity of early nephrectomy. The condition of the ureter probably explains the observation that vesical irritation is more marked in tubercle than in calculus. The importance of a bacteriological examination of the urine when these symptoms exist is obvious. It may be necessary to examine several specimens, as the bacilli may be few in number, and here the superiority of an electric-driven centrifuge becomes apparent.

Of hæmaturia as an initial symptom I have seen, or more correctly recognised, only one instance. A man, aged 37 years, was admitted into Guy's Hospital under my care on

Arris and Gale Lecture

ON

THE PATHOLOGY OF ACID INTOXICATION.

Delivered before the Royal College of Surgeons of England on March 16th, 1908,

BY F. A. BAINBRIDGE, M.A., M.D. CANTAB.,
M.R.C.P. LOND., D.SC. LOND.,

DEMONSTRATOR OF PHARMACOLOGY, ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.

MR. PRESIDENT AND GENTLEMEN,—I wish to thank you for the honour which you have conferred upon me in inviting me to lecture here to-day. Acid intoxication, or, to use a wider term, acidosis, is merely one aspect of disordered metabolism, and our knowledge of its pathology has progressed to a large extent side by side with our knowledge of metabolic processes as a whole; it seems desirable, therefore, to discuss acidosis rather as a phase of metabolism than as a separate pathological entity. Without attempting to cover the whole subject, I propose in the time at my disposal chiefly to consider the results of the more recent investigations. It is necessary at the outset to draw a distinction between acidosis and acid intoxication. The essential feature of acidosis is the occurrence of certain organic acids in abnormal amount in the blood and urine; the most important of these acids are lactic and β-oxybutyric acids, and their estimation in the urine furnishes the most accurate means of measuring the intensity of the acidosis. The term acid intoxication should be limited to conditions in which, in addition to acidosis, toxic symptoms, referable to the organic acids, make their appearance. Acidosis may be accompanied by diminution of the alkalinity of the blood, and the urinary excretion of ammonia is usually increased. Even in acidosis, however, the alkalinity of the blood remains remarkably constant, though it may be temporarily disturbed by a sudden production of acid; and a normal alkalinity of the blood may coexist, as Magnus Levy has shown, with a considerable degree of acidosis. And neither the total excretion of ammonia in the urine nor the ammonia coefficient (i.e., the proportion of the total nitrogen excreted as ammonia) necessarily or even usually corresponds to the *degree* of the acidosis.

It is true that in acidosis the output of ammonia may reach a very high figure; in diabetes the daily excretion is often 3·5 grammes, and the excretion of 10 to 12 grammes has been recorded by Stadelmann, while the ammonia coefficient may rise as high as from 20 to 40. There is no reason, however, to believe that the tissues specially produce ammonia in order to neutralise the organic acids which are present; ammonia is normally formed by the tissues in considerable amount, and the organic acids merely combine with it and so prevent the liver from converting it into urea. In severe acidosis the limited amount of ammonia produced in the body is inadequate to combine with all the organic acids, so that the excretion of alkalies and alkaline earths becomes excessive; if the acidosis diminishes these valuable bases are retained in the body until their excretion has fallen to the normal level, the output of ammonia does not sink *pari passu* with the lessened output of organic acids. Satta has published some figures which clearly illustrate this fact:—

Day.	Total nitrogen.	Nitrogen as NH_3.	Percentage of NH_3.	β-oxybutyric acid.
1	12·93	2·1 grm.	16·2	8·24 grm.
2	11·42	1·83 „	15·4	0·46 „
3	8·93	1·17 „	13·1	0·18 „

It is clear, therefore, that even in acidosis the ammonia excretion may be fallacious and that an implicit belief in the value of the ammonia quotient is not free from danger. In a fasting woman, studied by Bönniger and Mohr, the following figures were obtained:—

Fast day.	Total nitrogen.	Total NH_3.	Percentage of NH_3.	β-oxybutyric acid.
3rd.	6·59	0·49	6·12	8·4 grm.
9th.	5·40	1·33	20·23	8·2 „
11th.	5·16	1·09	17·38	6·2 „
16th.	4·06	1·24	30·57	17·6 „

Such figures indicate that for the correct interpretation of ammonia analyses several factors must be taken into consideration. Fohn has shown that a healthy man placed on a diet poor in nitrogen but of adequate caloric value may excrete from 10 to 12 per cent. of his total nitrogen as ammonia, and a high ammonia coefficient has long been known to accompany the acidosis of starvation, the highest ammonia coefficient ever recorded (namely, 66 per cent.) having been obtained by Nabethan in a fasting woman. The high ammonia coefficient observed in pernicious vomiting of pregnancy is in all probability the result of partial starvation, as is evidenced by the beneficial effects of carbohydrate food and the very low output of total nitrogen in the urine. And it should be clearly recognised that when the nitrogen intake is low a high ammonia coefficient may have no pathological significance.

In very extensive disease of the liver, also, the excretion of ammonia may rise quite apart from acidosis. Weintraud has found a high coefficient in extreme cirrhosis of the liver and the excessive output in acute yellow atrophy may be accounted for in the same way. But a very small fraction of healthy liver suffices to carry out normally the conversion of ammonia into urea. Pearce and Jackson, using hæmolytic sera, found that extensive necroses of the liver had no effect upon the excretion of ammonia relative to the total nitrogen; and in the experiments of Underhill and Kleiner with hydrazine the urine remained normal notwithstanding the intense fatty degeneration of the liver cells. Clinical observations also show that extensive disease of the liver may be present, for example, in eclampsia without any corresponding alteration in the excretion of ammonia, and that only in almost complete disorganisation of the liver does the ammonia coefficient rise appreciably.

These considerations have a direct application to the acidosis caused by lactic acid, since its appearance in the urine is often regarded as dependent upon disease of the liver, which consequently fails to oxidise the lactic acid. This belief rests partly upon experimental, partly upon clinical, evidence. Minkowski found that after removal of the liver in geese the urine contained large quantities of ammonium lactate, but as Leathes points out lactic acid is a normal intermediate product of metabolism, and when the ammonia fails to be converted into urea it combines with lactic acid, and therefore the latter escapes oxidation. A similar explanation also accounts for the appearance of lactic acid in the experiments of Salaskin and Galeski on the removal of the liver in dogs, but in addition the animals showed tetaniform convulsions, and, as we know, convulsions or violent muscular exercise cause lactic acid to appear in the urine, quite apart from disease of the liver. Moreover, neither the extensive injury to the liver produced by hydrazine poisoning nor the interference with its functions caused by Eck's fistula is followed by the appearance of lactic acid in the urine.

In man lactic acid occurs in the urine in acute yellow atrophy and occasionally in extreme cirrhosis or cholæmia; there is unfortunately no satisfactory method of estimating lactic acid in the urine, but the amount excreted in these diseases appears never to be very large. It is significant that lactic acid occurs in those diseases in which the ammonia excretion rises when the liver is so damaged that it can no longer form urea, and that the excretion of ammonia appears to be larger than that of lactic acid. It may fairly be concluded, I think, that lactic acid occurs in the urine in cholæmia or acute yellow atrophy, not because the liver fails to oxidise it, but because, as in Minkowski's experiments, it combines with ammonia and so escapes into the urine; and the acidosis due to lactic acid is merely a "secondary" acidosis devoid of practical importance. This view is fully borne out by our general knowledge of the metabolism of lactic acid. It is normally present in the blood and in

TUBERCULOSIS OF THE KIDNEY (*continued*).

MR. PRESIDENT AND GENTLEMEN,—In the first lecture I placed before you cases illustrating the early signs of renal tuberculosis and showed the condition of the kidney when removed. Except in one there was no enlargement to be felt, and in the instance where this occurred it appeared somewhat suddenly as a final symptom (Case 4).

Before offering some comments upon the points raised by these cases a word must be said of that form of renal tubercle which gives rise to a tumour. The large, moveable, painless, tuberculous kidney is too well known to need any but a passing reference. The cases are fairly common and those that have come under my notice have all given a history of attacks of pain extending over one to three years. In a typical case operated upon in 1902 and quite well in 1908 there had been frequent micturition in the early stages and then repeated attacks of pain. As the tumour enlarged the vesical symptoms ceased. The tumour could be seen moving on respiration, was lobulated, painless, and resembled a hydronephrosis. There were very little pus and albumin in the urine and no increase of urine or pus after an attack. The general health of these patients is on the whole good and they are able to work. These cases resemble hydro- or pyonephrosis in the length of the history, the character of the pain, the moveable and lobulated character of the tumour. I call attention to this, not as an early form of renal tuberculosis but as one where the diagnosis can now in all probability be settled by an examination of the urine.

Before considering the question of treatment I would call attention to certain of the early symptoms. Amongst these renal colic is perhaps the most interesting of all the initial signs of renal tubercle. The exact resemblance to that produced by a calculus cannot be better exemplified than in Case 2. Here was a man of 46 years, though not up to hard work yet looking in good health, seized with severe renal colic. And not only did the three attacks thus closely resemble calculous disease but the likeness was made still closer by the vesical irritation which followed. In Case 1, a young lady, aged 20 years, the long interval between the attacks—one year—points once more to the necessity of careful and routine examination of the urine if we are to discover and treat tubercle early. When renal colic occurs it would seem to indicate that excavation has taken place, whether in one small focus, as in Case 1, or in several, as in Case 2. I mean it suggests more than miliary tubercle and would support the decision to operate. This symptom was absent in Case 3, where the ureter was affected, so that this latter condition may exist without spasmodic pain. Regarding the value of renal colic as an indication of the stage and distribution of tuberculosis, it must have occurred at a very early stage in Case 1, for when the kidney was removed two years later the original focus was small. On the other hand, in Case 2, where the first attack occurred four months before removal, the specimen shows that the disease must have been in existence for a long time—two years or more. The curious abdominal attacks preceding by some two years the vesical symptoms in Case 4 must be grouped under this head.

Albuminuria, one of the early signs of renal tuberculosis, has perhaps not attracted sufficient attention. The association with vesical irritability especially should lead at once to an examination of the urine for bacilli, and again when the amount of albumin is more than can be accounted for by the pus. In Case 4 the cystoscope pronounced the kidney and ureter free from disease but the large amount of albumin led us to fear bilateral renal infection. That it came from one side was proved by its disappearance after nephrectomy. The amount of albumin does not appear to bear any uniform relation to the extent of disease, nor apparently to the form which it takes. Thus in Case 1, with the tuberculous process limited to the lower pole, the albumin was at times abundant. In Case 3, with far more extensive disease but without excavation, the albumin was never excessive, though always more than could be explained by the pus. This is the main point as regards albumin—the proportion to the pus. The contrast was most marked in Case 4, where the pelvis of the kidney was obliterated and the tuberculous foci were shut off from the ureter. In Case 2, with destruction of the lower third of the kidney and recent miliary tubercle, the albumin was never abundant. The fact that miliary tubercle is a painless condition, and that extensive destruction may take place without pain, intensifies the importance of a bacteriological examination of the urine when albumin is present without a general cause being found.

Vesical and urethral irritability without implication of the bladder were in one case (Case 3) the only symptoms up to the time of operation. There was just a suspicion of right renal infection, but only with the aid of the cystoscope was accurate diagnosis possible. This symptom in another case (5) had existed for more than a year, and at one time was thought to be a reflex effect of hæmorrhoids, which were in consequence removed, but without benefit. It was sufficient to limit this patient's activities and it will be remembered that the next symptom was hyperpyrexia without any localising sign. Perhaps the cystoscope might have indicated the kidney affected and saved the laparotomy, but the case occurred in 1897 before I was personally acquainted with the value of this method of examination.

As might be expected when the bladder is involved, the vesical irritability is more pronounced, and so no doubt it is, but, on the other hand, as shown by Case 4, the vesical irritation may be quite moderate where marked tuberculosis exists. In more than one instance of renal tubercle, without vesical disease, it was this symptom that alone compelled attention. That the bladder is tolerant of tuberculous pus is shown by several cases. In some the infective material must have entered the bladder for two years without causing irritation; in others probably for a longer period; while in other cases I have seen quantities of almost pure pus passed with little vesical irritation. This point is worth noting in view of the possibility of this complication being unduly urged as an argument for immediate operation.

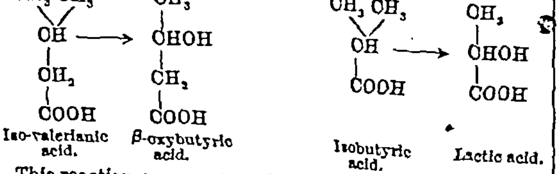
At what period in the course of renal tuberculosis does vesical irritation arise and to what is this symptom due? An examination of the specimens in the light of the history of these cases shows that renal tuberculosis may reach an advanced stage without causing vesical symptoms. For example, in Case 2, and probably also in Case 3, the renal condition had existed some time before the urethral pain arose. It would appear, then, that this symptom, when persistent, indicates advanced disease of the kidney. Again, it is to be noted that in all the cases operated upon the ureter was involved and that where the cystoscope was employed the lips of the orifice were everted and swollen and in one studded with tubercles. It is probable that the persistent irritation indicates extensive ureteric infection. That the mere fact of ureteric infection is in itself not the cause is shown by the disappearance of the pain after nephrectomy. The passage of the urine down a narrowed channel appears to be the explanation of this pain. Evidently a small plug of mucus will be sufficient to cause severe colic, as it did in Case 2. The above reasoning is sufficient to show the importance of this symptom, as indicating, when persistent, advanced disease and pointing to the necessity of early nephrectomy. The condition of the ureter probably explains the observation that vesical irritation is more marked in tubercle than in calculus. The importance of a bacteriological examination of the urine when these symptoms exist is obvious. It may be necessary to examine several specimens, as the bacilli may be few in number, and here the superiority of an electric-driven centrifuge becomes apparent.

Of hæmaturia as an initial symptom I have seen, or more correctly recognised, only one instance. A man, aged 37 years, was admitted into Guy's Hospital under my care on metabolism in such a way that sugar is either not formed from proteid or is burnt up by the tissues, and that the increased supply of energy thereby obtained prevents the formation of the acetone bodies. These observations are extremely suggestive and may not only furnish a clue to the means by which carbohydrate food abolishes acidosis but also throw some light on the interaction of the various food products within the cell. But, whatever may be its explanation, there is no doubt that the acidosis of starvation results from a lack of carbohydrate. Waldvogel has suggested that in diabetes acidosis is due to an impaired oxidative power of the cells of the tissues. There is, however, no definite evidence that the acidosis of diabetes differs essentially in its origin from that of carbohydrate starvation in healthy individuals except that the starving man can utilise any sugar which is formed in the body from proteid, whereas the diabetic patient is unable to do so. From this point of view diabetes is a condition of prolonged carbohydrate starvation, and the importance of the acidosis lies in the fact that it ultimately leads to acid intoxication and coma. According to Külz coma is the natural termination of diabetes, and the more severe the acidosis the more rapid the course of the disease. It is most desirable, therefore, to ascertain what are the more immediate precursors of the acetone bodies and how far the acidosis can be influenced by diet or in other ways.

---

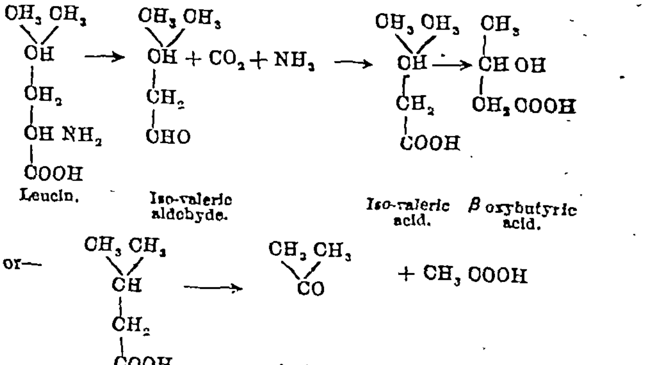
[1] Lecture I. was published in THE LANCET of March 21st, 1908, p. 833.

A considerable body of facts bearing on this question has been obtained but partly on account of the wide spontaneous variations in the urinary excretion of diabetic patients from day to day, partly on account of the difficulties inherent to metabolic observations on man, the results are not always concordant or easy to interpret. In the first place it appears that the bulk of the β-oxybutyric acid is derived fairly rapidly from ingested food. Allard found that an occasional "fast day" markedly lessened the output of acetone bodies and that the beneficial effect lasted for several subsequent days. In the case of a severe diabetic in nitrogenous equilibrium, a fast-day reduced the excretion of β-oxybutyric acid from 17·3 grammes to 2·9 grammes; the ammonia fell from 5·8 grammes to 3·1 grammes. Equally definite results were obtained in other cases. Secondly, there is no doubt that the lower fatty acids notably and quickly increase the output of the acetone bodies. This was first demonstrated by Schwarz for butyric, cupric, and iso-valerianic acids and has been repeatedly confirmed; and the conversion of these acids into β-oxybutyric acid occurs so readily and supplies so little energy to the body that their exclusion from a diabetic diet seems desirable. Some light has been thrown on the chemical changes involved in this process by the observations of Baer and Blum. They administered a number of fatty acids to severe cases of diabetes, kept on a uniform diet, and found that 20 grammes of iso-valerianic acid increased the output of β-oxybutyric acid from 1·5 grammes to 9·8 grammes, whereas isobutyric acid yielded lactic acid. They conclude that a split occurs at the β-carbon atom and that a methyl group separates off, leaving a straight chain acid.



This reaction represents a chemical process which has not hitherto been observed in the body. It is highly probable, however, that β-oxybutyric acid is formed not only from the lower but also from the higher fatty acids. The modern conception of fat katabolism is that the saturated fatty acids derived from the food or from the fat depôts in the body are converted by the liver into fatty acids with several unsaturated linkages; these unsaturated fats then pass to the muscles where their oxidation is completed. Fatty acids with three double bands have been found constantly in the liver by Hartley, and the fat of the heart muscle appears to be of the same nature. Although the liver can probably form β-oxybutyric acid most of the energy of the body is furnished by the muscles, and it is reasonable to suppose that the final stages in the oxidation of fat, whose combustion supplies so much energy, is carried out chiefly in the muscles. It is quite possible that the breakdown of the unsaturated fatty acids does not occur by the oxidation of one or two carbon atoms at a time, but that the fat molecule, rendered unstable by the presence of several double linkages, suddenly breaks up into a number of fatty acids of comparatively small molecular weight. If butyric acid is one of these acids the rapid production of β oxybutyric acid from higher fats is easily intelligible and the speedy increase of the acetone bodies, when oleic or stearic acid is given to diabetic patients, may be thus interpreted. Apart from butyric acid, however, the rest of the fat molecule appears to undergo complete oxidation. Although fats are the most important source of the acetone bodies the advance in our knowledge of proteid metabolism has again brought into prominence the possible formation of β oxybutyric acid from proteid. It is now believed that during digestion the proteid molecule is largely broken down and that the products—chiefly amino acids—are again synthesised by the tissue cells. Lang has shown, also, that the various tissues have the power of denitrifying amido acids, leaving a simple fatty acid. It is possible, therefore, that the final stages of fat and proteid katabolism may proceed along similar lines. There is, at any rate, definite evidence that leucin can give rise to the acetone bodies. Dakin has shown that when leucin is oxidised *in vitro* by hydrogen peroxide, acetone, iso-valerianic aldehyde, iso-valerianic acid, and ammonia are produced. And Strecker long ago found that in the presence of alloxan iso-valerianic acid is formed from leucin. Alloxan probably exists normally in the liver, and Strecker's observation may have some bearing on the work of Embden, Almagia, and Salomon. They perfused the surviving liver of dogs with blood, to which various proteid derivatives had been added, and estimated the amount of acetone formed. The perfusion of normal blood yielded small amounts of acetone, and the addition of alanin, glycocoll, and glutaminic acid was without effect. But when leucin or iso-valerianic acid was added to the blood they obtained a considerable quantity of acetone, and β-oxybutyric acid was still more effective. Their method of estimating acetone is open to criticism, since so many substances give the iodoform reaction, and it is not certain that they obtained acetone by the perfusion of normal blood. But when leucin was added to the blood, acetone was actually isolated as dibenzylacetone. Finally, Borchardt in the case of a normal man deprived of carbohydrate and Baer and Blum in a diabetic patient found that leucin increased the output of both acetone and β-oxybutyric acid.

The conversion of an amido acid into the aldehyde of the lower acid, with loss of ammonia, is a very general reaction, and the next stage may be the splitting of a methyl group and the formation of β oxybutyric acid, and finally of acetone. The production of acetone in Embden's experiment is a little difficult to understand, unless β-oxybutyric acid is an immediate product, since, as far as is known, acetone is not normally formed in the body; possibly the transformation of leucin normally ceases with the formation of β-oxybutyric acid, and the production of acetone in the perfusion experiments is not strictly physiological. The probable sequence of the chemical reactions may be represented thus:—



The different proteids vary greatly in the amount of leucin which they yield on hydrolysis. Muscle proteid has not been analysed, but casein yields 10 per cent. of leucin, egg albumin and gliadin (of wheat) 6 per cent., and gelatin only 2 per cent.

When one considers the large amount of proteid often was still limited, and the marked improvement in others, still further support the operative treatment.

Nephrectomy in tuberculosis may be considered as a primary or a secondary operation. In general a patient can bear removal, a preliminary nephrotomy being used for those cases too ill to bear the full operation and for those where it is not possible to estimate the secreting value of the opposite kidney with accuracy. In advocating early nephrectomy so soon as destructive disease has been recognised, either by the usual clinical evidence or by the use of these newer methods referred to, certain questions arise, answers to which are afforded by the cases related in the first lecture.

Is tuberculosis of the bladder a contra-indication to nephrectomy? The answer lies in the reply given by the cystoscope as to the distribution of the vesical infection. When the disease is situated round the ureteric orifice of the affected side, the other appearing normal, and a clear efflux is visible, removal of the kidney is clearly the right practice. In Case 1 with fairly extensive vesical infection complete recovery has followed nephrectomy, and in Case 4, where the tuberculous infection was some distance from the ureteric orifice, there is every prospect of complete recovery. Looking to the recoverability of vesical tubercle I see no objection to nephrectomy, even with multiple foci in the bladder, provided one kidney is healthy, or at least so far as can be discovered. It is obviously difficult to be quite sure on this point, seeing that miliary tuberculosis is painless and that the changes in the ureteric orifice do not occur, as far as I am aware, till the ureter is involved. If examination with the cystoscope is not available prolonged vesical and urethral irritation with painful micturition must not be taken as proof of vesical tubercle. These symptoms may indicate ureteral infection only.

Does slight disease of the other kidney—an amount indicated by a few bacilli and a little albumin in the urine collected from this side—contra-indicate nephrectomy where the other is obviously tuberculous? Two main considerations arise here—the distress caused by the obviously affected kidney and the curability of renal tuberculosis. When one kidney is practically destroyed and contributing little urine, is causing pain, and disturbing the rest, its removal is surely justifiable. If both kidneys are enlarged then operation is out of the question. If renal tuberculosis, taken in the early stages, is recoverable, then the removal of a cause depreciating the general health must contribute to recovery. On this view nephrectomy comes under the general question of the surgery of generalised tubercle where removal of a suppurating focus promotes recovery in others, as for example, amputation of a tuberculous knee for the relief of pulmonary disease. Again, the removal of further infection is obviously a sound practice and indeed is essential if the other kidney is to recover at all. There is therefore it seems to me good reason for removing an obviously tuberculous kidney, causing local and general symptoms, even when the other kidney is infected, but in an early stage, provided also that the general condition of the patient justifies such a course. If the ureteric orifice of the sounder kidney indicated disease of the ureter then any operation, except perhaps nephrotomy, for the relief of pain, would be out of the question.

Ureterectomy.—The next important question is as to whether the ureter should be removed at the time of the nephrectomy or later, or left altogether. To leave a tuberculous ureter seems at first sight to be illogical and as likely to determine further infection. Looking to the cases recorded in the first lecture it will be seen, however, that complete recovery of a tuberculous ureter may take place after the kidney has been removed. In Case 1, with coincident bladder infection, the ureter was not removed as a primary step with the kidney in order not to prolong the operation and the narcosis, seeing that in the recent attack of renal colic the urine had been scanty. This young lady is apparently quite well and is certainly free from all signs of ureteral or vesical tubercle. In Case 2 an opportunity was obtained of examining the ureter nine months after the nephrectomy. Here the ureter was removed to relieve the loin sinus, to which, however, it did not contribute, for the upper end was closed. The ureter was still thicker than normal but not nearly so large as at the time of the nephrectomy. The microscopical section showed remnants of a tuberculous process quite distinctly but no active changes. The slight hectic temperature, to relieve which the ureterectomy was performed, was unaffected by its removal. Though in itself harmless it is quite possible that such a ureter might set up infection in the lymph glands. On the other hand, there are cases where the ureter is the cause of persistent symptoms. In Case 5 the ureter was found large and rigid and was left. Persistent vesical irritation suggested tuberculosis of the bladder or of the remaining kidney. Removal of the ureter was followed by complete recovery. This was done in 1898 and the patient is still enjoying the best of health. The ureter shows dilatation of the channel, with suppuration and thickening of the wall. In Case 3 the ureter was removed at the same time as the kidney, and recovery was more rapid than in most of the others. In this case urethral irritation was the only symptom complained of, and I am inclined to think might have persisted had the ureter not been removed.

While, therefore, it may be said to be established that a tuberculous ureter may recover, and mostly *does* recover, I am myself inclined to the view that the better practice is to remove it, if possible, at the same time as the kidney. It is particularly desirable to do so when there is coincident disease of the bladder and when the ureter is found to be enlarged and rigid. Where the wall is less diseased and retains its supple characters spontaneous recovery is more certain to occur. In conclusion, while advocating coincident removal of the ureter as calculated to promote more rapid recovery it must be admitted that ureterectomy is not essential to ultimate recovery, and that it must be postponed for further consideration whenever the additional strain on the patient might be injurious. As regards the removal it need not prolong the operation to any serious extent if performed as I suggest.

Removal of the ureter.—A few particulars may not be out of place with regard to this matter. The incision is best made so as to separate the muscles below the anterior superior spinous process, as in the operation for appendecectomy. The peritoneum is raised and with it goes the ureter, so that this structure must be sought on the anterior wall of the cavity and close to the spine. Being thickened, it can as a rule be easily felt, and indeed is not difficult to find when normal. When removal follows immediately upon nephrectomy great assistance is obtained by pulling upon the lumbar end, the tight band being recognised at once. Later the ureter is drawn tight by the lumbar scar, lies nearer the spine, and may cost a little time in the finding. The best plan of dealing with the ureter is after separating it down to the bladder to open the channel by an incision going half way through the wall. The vesical end is now curetted and rubbed with pure carbolic acid, the undivided half thus being used to keep the parts in view. Then a catgut ligature is applied and the division completed. I have usually inserted a small rubber drain surrounded with a layer of gauze, but this is, I believe, unnecessary if the end be dealt with as above described. In secondary ureterectomy if there be a loin sinus this should be enlarged and the end detached by the finger working with that from below. If the loin incision has closed, I think it a better practice to reopen this region than to divide the muscles in front, as a stronger abdominal wall results.

What position should incision and drainage occupy in the treatment of renal tuberculosis? It may be necessary to make a preliminary nephrotomy, either because the patient is too ill to bear removal or to make more certain as to the secreting value of the opposite kidney. The value of this measure was well illustrated by Case 5, where the general infection with rigors, &c., was relieved by drainage, making a subsequent nephrectomy almost free from anxiety. In Case 4 the question was important, for here there was sudden enlargement of the kidney with escape of pus into the bladder, hectic fever, and rapid decline of the general health. However, as these symptoms were of short duration the full operation was carried out.

When uncertainty exists as to the value of the opposite kidney preliminary nephrotomy will afford much information, especially in those cases where the ureter is not obstructed. When the destruction is found to be extensive extirpation can be carried out at once, but where there is uncertainty the removal may be postponed and the comparative values of the kidneys ascertained by collecting the urine from the loin and the bladder. If the general condition does not improve we may have to rest content with nephrotomy leaving a loin sinus. If, however, as is more often the case, improvement results, how soon may the kidney be removed? That there is no immediate hurry from the fear of vesical infection is well shown by Case 5, in which the kidney was that if the acidosis lessens the fixed bases are spared and retained in the body and the ammonia excretion remains high. It is of importance, too, to bear in mind in this connexion the observations of Forster, Lewin, and others that animals whose diet is ash-free, but otherwise normal, soon show signs of perverted metabolism, and that death ensues in a few weeks. The symptoms are chiefly referable to injury to the central nervous system and were regarded by Bunge as the result of an acid intoxication.

Obviously even a trifling daily loss in bases, a loss so small as almost to escape observation, may in course of time rob the tissues of much of their bases; and the excretion of bases in the diabetic patients studied by Magnus Levy was much larger than those of normal individuals. Observations on the total intake and output of bases in diabetes are lacking but it seems very probable that there is a gradual depletion of the alkalies in the tissues, and that a point is ultimately reached when the alkali content of the tissues is insufficient for normal metabolism and symptoms of intoxication occur. It is possible, of course, that the gradual loss of alkali simply lessens the amount of base available for the neutralisation of acid, and that the ultimate result is an acid intoxication due to the diminished alkalinity of the tissues. On the other hand, it is not fair to assume that a deficiency of alkali is synonymous with a relative acidosis. Although we do not know how or why inorganic bases are essential to the bioplasm, their importance for normal metabolism is a matter of common physiological knowledge, and no one imagines that calcium, for instance, the presence of which is necessary for the normal contraction of the muscles, acts solely in virtue of its being a base. It seems to me extremely probable that the lack of some or all of the bases may primarily disturb the course of metabolism, quite independently of the alkalinity of the tissues; and after all the alkalinity of the tissues does not depend solely upon their inorganic constituents, since the proteins can apparently act either as weak acids or as bases. On this view, even the diminished alkalinity of the blood in coma may be interpreted as due to a final effort on the part of the tissues to satisfy their need for base. It is not sufficient to supply the body with sodium carbonate, and the value of the treatment of diabetes with alkali might be much greater if all the bases required by the body were administered to diabetic patients. An accurate knowledge of the amount and character of the bases present in diabetic tissues would also be of extreme value.

POST-ANÆSTHETIC ACETONURIA.

Acetonuria occurs in children in a variety of conditions, but I can only refer briefly to one—namely, the acetonuria following anæsthesia. It seems to have been first noticed by Becker in 1895; he examined 251 cases and found acetone or diacetic in 167. The condition appeared to be independent of the nature of the anæsthetic or the duration of the anæsthesia and was more severe in cases of pre-existent acetonuria. While children were the most liable, adults were not exempt. These observations have been generally confirmed by English and American writers, although most of them regard chloroform as the anæsthetic most likely to cause acetonuria. In the majority of cases acetonuria is the only symptom, but occasionally definite toxic symptoms occur and death may ensue. The most characteristic symptoms are intense thirst, vomiting, restlessness, and finally coma; air-hunger has been observed in some cases. The amount of acetone in the urine may reach a high percentage; Beesley found from 20 to 60 milligrammes per 100 cubic centimetres, an amount comparable to that in fairly severe diabetes. β-oxybutyric acid has sometimes been estimated and in one case Waldvogel obtained 2·5 grammes in 24 hours. Although the literature of the subject is extensive, no estimations seem to have been made either of the alkalinity of the blood or the ammonia excretion in the urine. Post mortem the liver has been constantly found to exhibit intense fatty infiltration with patches of necrosis, and Telford observed fatty change in the cardiac and other muscles.

The interest of post-anæsthetic acetonuria lies in the appearance of symptoms of acute intoxication in certain cases and in its relation to other forms of acetonuria. The power of the anæsthetics to interfere with metabolism as a whole, and their toxic action upon protoplasm are well known. Our knowledge of their exact mode of action is scanty, but, broadly speaking, they inhibit metabolic processes, as is indicated by Loewry's observation that they diminish the intake of oxygen by the tissues; and Moore and Roaf consider that they lessen the metabolic activity of the tissues by combining with the tissue proteins. The metabolic disturbance caused by anæsthesia is usually trivial, because the anæsthetic speedily leaves the tissue when the anæsthesia comes to an end. The severe toxic symptoms which occasionally follow anæsthesia can only be explained, I think, by assuming that the anæsthetic remains in combination with certain tissues, since doses of anæsthetics which are too small to induce anæsthesia if frequently repeated will produce similar metabolic disturbances in animals. The varying susceptibility or "idiosyncrasy" of different individuals to the action of all poisons, including anæsthetics, must be acknowledged, even though it cannot be explained. If it be admitted that occasionally the anæsthetic remains in combination with the tissues the occurrence of acetonuria is the inevitable outcome of their lessened oxidative capacity. Post-anæsthetic acetonuria is, in fact, closely analogous to phosphorus poisoning, in which the oxidative capacity of the tissues is primarily damaged. The inhibition of metabolism by anæsthetics results in the incomplete combustion of fat and β-oxybutyric acid and its products appear in the urine, and the failure of the muscles to burn up fat leads to its accumulation in both the muscles and the liver. Fatty infiltration of the liver can occur with remarkable rapidity and there seems to be no reason to believe that when symptoms of intoxication occur after anæsthesia the liver was previously diseased. Equally severe fatty infiltration of the liver may be found in other conditions, not only without the appearance of toxic symptoms but even without any acetonuria.

Although the acetonuria depends upon the imperfect combustion of fat by the tissues, it is by no means clear that the toxic symptoms are due to the acetonuria. I have found in other conditions in which no symptoms of acid intoxication were present, an amount of acetone equal to that observed in the cases of post-anæsthetic intoxication. Unfortunately, nothing is known as to the alkalinity of the blood and the excretion of ammonia in these cases, and the facts at our disposal are insufficient to exclude acid intoxication. But it does not seem probable that the toxic symptoms following anæsthesia are due to an acid intoxication. The toxic action of anæsthetics is known from animal experiments to affect not only the oxidation of fat but metabolism as a whole, and closely resembles that of phosphorus. In both cases acetonuria occurs and the liver shows morbid changes, and whatever may be the significance of post-anæsthetic intoxication it seems unjustifiable to refer the symptoms either to the liver or to the acetonuria.

I ought, perhaps, to allude to carbohydrate starvation as a factor in post-anæsthetic acetonuria. Waldvogel pointed out that patients who took carbohydrate freely before and after operation seemed to be less liable to acetonuria. And it is probable that post-anæsthetic acetonuria may sometimes arise solely from carbohydrate starvation, especially in those cases in which, owing to fever or vomiting, but little food is taken for some days before operation. The metabolism of children appears to be less stable than that of adults, and they react very quickly to a lack of carbohydrate, possibly because their reserve supply is relatively small. But it is obvious that, apart from previous carbohydrate starvation, the tissues, poisoned by the anæsthetic and unable to utilise fats (and possibly proteids), will speedily use up the available carbohydrate in the body, and a plentiful supply of carbohydrate, not only when symptoms of intoxication occur after anæsthesia but also as a routine preventive measure before operation, appears to be the rational treatment of post-anæsthetic intoxication. It must be remembered, however, that there is no absolute proof that in these circumstances the metabolism of carbohydrate is normally carried out; the frequency of glycosuria, in fact, points in the opposite direction.

INTERNATIONAL PRIZE FOR OPHTHALMOLOGY.—The Royal Hungarian Minister of the Interior has offered the sum of 1000 crowns as a prize to the author of the best work on the Etiology of Trachoma. All work which is original, whether in manuscript or published for the first time in 1907 or 1908, will be eligible for the competition, provided it is in English, Hungarian, French, or German, and that it is received by Dec. 31st, 1908, at latest by the Minister of the Interior, Belügyministerium, Budapest, Hungary. The jury will be appointed by the Minister and its verdict will be announced at the inaugural sitting of the forthcoming International Congress of Medicine.

bacteria are "picked up" by the leucocytes, but it seems never to have been proved that this process is *always* pernicious to the bacteria. It cannot be denied—what is emphasised by several authors—that the rôle of phagocytosis as a factor of immunity is still without clinical confirmation. The next assumption is that experiments on phagocytosis made *in vitro* are adequate expressions of the phagocytic processes in the organism. It is said, for instance, that the more virulent the bacteria are in the organism the more the leucocytes decline to take them up. But the opsonic doctrine does not in any way pay attention to the virulence of the bacteria.

We will now discuss the value of the estimations of the opsonic index. At our disposal we have a series of tuberculo-opsonic indices, measured both on healthy persons and on patients suffering from lupus. These estimations were made from Jan. 21st to July 16th, 1907. After this date we estimated no opsonic index but still continued the inoculations with T.R.

We arranged our experiments in the following way. The blood was as a rule withdrawn between 10 A.M. and 12 noon. The slides were "put up" some hours later. The next day they were counted by one of the assistants of the laboratory, Mrs. Maar, who had been trained for a month in the counting. All the slides with the exception of those from two days were counted by Mrs. Maar. When once counted a slide was never counted over again even if the result seemed to us to be ever so unlikely. Before Mrs. Maar received the slides we always mixed slides from patients with others from healthy persons in such a way that she never knew to whom the slides which she was counting belonged. This was done in order to avoid the immensely great risk of self-suggestion in estimating the opsonic index which no counter can get rid of if he or she knows to whom the slide which is being counted belongs.

It is known that Sir A. E. Wright is accustomed to "pool" the serum from several persons and in this pooled serum to count 100 leucocytes, which count he then reckons as unity. We have not done this, as it did not seem to us sufficiently exact; instead of this we reckoned as unity the average phagocytic count of, usually six, healthy persons—i.e., we used six healthy sera and counted in each the number of bacteria contained in 100 leucocytes, which is, of course, equivalent to the number of bacteria contained in 600 leucocytes. The resulting number of bacteria divided by 6 was taken as unity, for we always counted 100 leucocytes in each slide of blood obtained either from a patient or a healthy person. We did this in order to get exactness as far as possible. We also in some cases pooled the six sera after the manner of Sir A. E. Wright, and in this table we see in the first column the phagocytic count in 100 leucocytes of the pooled serum of six persons and in the second the phagocytic count in 600 leucocytes divided by 6.

I.	II.	I.	II.	I.	II.
221...	170	246...	244	206...	209
194...	110	176...	140	174...	192
141...	121	158...	157	145...	133
211...	143	144...	203	228...	255
186...	224	151...	260	361...	316
195...	229	218...	169	199...	214
212...	218	172...	149	224...	193
151...	152	272...	317	244...	334
154...	159	140...	145	138...	161
377...	242	221...	247	178...	246
212...	198	141...	123	97...	95

Of course, Column I. ought to correspond to Column II., but as we saw that it was not the case we chose the more difficult estimation of the 600 leucocytes as being more exact. As an average the content of tubercle bacilli in each leucocyte was from 2 to 4.

It seems quite clear that the basis of the use of opsonic index determinations must be the exactness with which the opsonic index is determined in healthy persons. This "opsonic index of the healthy" has exactly the same value as any other unit of measurement.

Here where we are speaking about exactness we wish to emphasise that the opsonic doctrine is a doctrine of numerical observations. Numbers can only be judged scientifically in accordance with the "theory of observation" (law of error). With regard to this theory, referring to the special authors,[1] we only wish to call to the mind three chief points which may hereafter be of some use to us.

1. If we have two groups of homogeneous observations and if we wish to know with what exactness the observations are made, it is necessary not only to determine the mean of each group but also the "mean error."[2] The mean in itself gives no idea of the exactness. This is easy to be seen from the following example. If an observer examines a serum six times, and each time finds the index to be 1·00, the mean of the six indices is 1·00. If another observer examines the same serum also six times and finds the indices to be 1·4, 1·2, 1·0, 1·0, 0·8, 0·6, the mean is also 1·00, but the exactness is far less (i.e., the mean error is greater). As it is not possible to use the mean as a measure of the exactness it is also impossible to use the "extreme limits" ("the greatest variations" between the indices of series of observations) as a measure of exactness. Suppose we have two series of observations of the same exactness, one with 10 observations, the other with 1000 observations. Then there will be in the last series more higher and lower results than in the first series with only 10 observations. By estimating the exactness by "the greatest variation" the last series would seem to be of a less value than the first, in spite of the fact that the exactness of the two series is the same.

2. Where an observer has a mean of a series of observations which are repetitions (observations in which many disturbing causes unknown to the observer and of small individual effect neutralise one another in the mass) he is only absolutely sure that a new observation is influenced by a predominant cause (for instance, in our examination T.R.) if this observation deviates from the mean more than four times the mean error (in the positive or the negative direction).

3. A series of observations will distribute themselves in a typical way according to the law of error. The distribution is as follows: (mean error = μ in percentage of mean); within a distance in positive or negative direction of—

½ μ from the mean fall 383 pro mille
1 μ " " " " 683 " "
2 μ " " " " 954 " "
3 μ " " " " 997 " "
4 μ " " " " 999·94 "

We have 673 times determined the tuberculo-opsonic index of healthy adults—219 times from 15 healthy men and 454 times from 33 healthy women. We found that the mean of these 673 indices was 1·00,[3] and that the mean error of the individual estimation was 0·19. If the healthy persons have a constant index this mean error (0·19) is like the mean error of the measure method. If the indices of the healthy persons are not constant this mean error comprehends as well the error by the measuring as the error depending on the not constant indices. The mean error of the measure method (i.e., how exact it is possible to estimate on the whole the indices) has only a theoretical interest. The mean error that also pays regard to the possible variations in the indices of the healthy person has the practical interest. As our investigations covered a period of five months, and as it, *a priori*, is likely that the exactness grows with the time (i.e., with the greater experience), we have divided these indices into four groups, each of 30 days. At the same time we have distinguished between males and females.

TABLE I. (*Males*).

[1] Bowley: Elements of Statistics, p. 261, *London*, 1901. (The book requires a good deal of mathematical knowledge.) Herman Olsen in Brauer's *Beiträge zur Klinik der Tuberculose*, I. Supplementband, p. 24-35, gives a quite popular sketch of the chief points of the law of error.

[2] Bowley calls it "error of mean square" or "standard deviation," loc. cit., p. 285.

[3] That the mean index of healthy people is 1·00 is a simple consequence of the way in which the unity is estimated.

Feb. 20th, 1907, with a history of frequent micturition for five weeks, beginning quite suddenly with hæmaturia. He passed large quantities of blood for three weeks, and when admitted he had pain at the end of the penis and along the urethra, increased on micturition. Nothing was found on examination of the bladder by sound or cystoscope. The man at first passed urine every few minutes with great pain. There were some pus and albumin in the urine with tubercle bacilli. In three weeks with ordinary treatment the symptoms were much relieved and he could hold his urine for an hour. On March 15th he had the first injection of tuberculin and regularly attended under Dr. J. W. H. Eyre for this purpose as an out-patient. In six months this man had grown so stout and well as to be quite unrecognisable. All symptoms had long disappeared and the urine was free from pus and bacilli. I have no proof that this was renal tuberculosis but the clinical history suggests ulceration of the summit of a pyramid.

A routine examination of the urine for tubercle bacilli when small quantities of albumin and pus are found without renal or vesical symptoms, but associated with ill health and anæmia, will no doubt in the future discover many cases of early tuberculosis of the urinary tract. There can be little doubt that tubercle bacilli were present in Cases 1 and 2 long before the attacks of renal colic. The next point in the investigation of such a case is to discover if possible which kidney is affected by means of the cystoscope, or segregation, or other methods. The ureteric orifice will not exhibit characteristic changes till the ureter itself is affected. It may therefore be impossible to be quite sure which kidney is affected, as catheterism of the ureter is generally admitted to be dangerous in the presence of infection, and segregation is not completely to be relied upon. In the absence of localising evidence for treatment we must rely upon general methods and tuberculin injections, and it will be valuable in the future to know how far such treatment is successful. There seems no reason why renal tubercle taken early should not recover, and it is probable that among the cases of slight albuminuria treated on hygienic lines with good effect there have been instances of tuberculosis.

How long are we justified in waiting after tuberculosis has been localised in one kidney? That there is no necessity for immediate nephrectomy is shown by the cases recorded in the first lecture. The two complications—viz., infection of the bladder and of the other kidney on the one hand and dissemination of tubercle on the other—are certainly long delayed, and in many cases, extending over some years, never occur. Where, therefore, the tubercle bacilli are few in number, the albumin and pus variable and often small in amount, and where vesical irritation is quite bearable, the bladder healthy, and the ureteric orifice normal, postponement is justifiable, and how far complete recovery can be brought about under such conditions has yet to be ascertained. When the ureteric orifice shows positive evidence of disease operation should no longer be delayed.

Is the condition of the kidney any guide to expectant treatment? Roughly, there are two forms of renal tuberculosis: that where the products of destruction are retained, giving rise to a painless moveable tumour in the presence of good general health, and that where the products escape and the kidney, though somewhat enlarged, as in Case 3, may not be so clinically. In both the ureter is involved. In the first the bladder is less likely to be infected, though the vesical irritation may be quite as troublesome as in some of the second class.

These being the facts, which kidney gives the most favourable prognosis? An answer demands a more complete acquaintance with the later history of both classes of cases than we possess, especially of the second. The tumour cases, being so obvious, have been observed and spontaneous recovery, either by caseation or escape of the contents, is known to occur. So far as I know we must wait for the later history of the second group treated without operation. There is good reason for believing that cicatrisation of even extensive disease may occur, as in Case 2, leaving much of the kidney healthy. On the other hand, the danger of vesical and renal infection point to this variety causing more danger than that where the products are encysted.

Attention has been called to the well-established observation that both kidneys are rarely affected at the same time. Renal tuberculosis is in fact generally unilateral. The recognition of this distribution of the disease is of prime importance in considering surgical treatment, and therefore the means at our disposal for ascertaining the incidence of the disease become of the greatest moment. In a great many cases the clinical evidence is sufficient; there is pain on one side, as in Cases 1, 2, and 4. Again, there is, in addition, in the acute type, enlargement of one kidney. In Case 3 these signs were absent, and except for the newer methods of investigation operative treatment would have been delayed. It is beyond the scope of this lecture to enter into an examination of the value of segregation, cryoscopy, cystoscopy, &c. These questions have been recently discussed before the society, and it is sufficient to acknowledge the essential help afforded by cystoscopy in the management of these cases. Of the various methods this certainly seems the most reliable, but demands, like similar modes of investigation, constant practice, and most of us will have to rely for interpretation and guidance upon those specially skilled in the use of the cystoscope. It is easy enough to recognise gross changes and to see a calculus, but to pronounce from the appearance of the ureteric orifice one or other kidney in a sufficiently morbid state as to demand its removal requires more than a casual acquaintance with this mode of examination.

The diagnostic value of cystoscopy can hardly be exaggerated in renal and vesical tuberculosis. Without the information afforded by this method more than one operation referred to in these lectures would have been delayed or abandoned. The cystoscope, in fact, has become as essential in investigating diseases of the kidney and bladder as the ophthalmoscope in diseases of the fundus oculi and brain or the laryngoscope in diseases of the larynx. Though not the only method of determining the condition of the kidneys it seems to be the most satisfactory. When I look at my nephrectomies, in the "nineties," for instance, and even up to 1905, the routine practice was to ascertain by opening the abdomen the condition of the opposite kidney. Before I had decided for myself to put aside the abdominal route it was very convenient to explore through the incisions made for nephrectomy. When the loin route was decided upon it became my routine practice to make an opening through the opposite rectus and examine the kidney. In one instance bilateral cystic disease was found, only one kidney giving clinical evidence of enlargement. In another a horseshoe organ was found and operation abandoned in both. I do not mean that in every case such exploration was necessary. When, for instance, the kidney formed a large tumour containing pus, and clinically it was pretty clear that it secreted little or no urine, the abdominal exploration was dispensed with. When the cystoscopic examination cannot be made by an expert, abdominal exploration still remains the best means of obtaining the requisite knowledge. There are conditions, too, where the cystoscopic appearances must be doubtful, or even misleading, as in Case 4 reported in these lectures, where the ureteric orifice gave no indication that the kidney was tuberculous. Yet the ureter and kidney must have been diseased in October when the second examination was made, for the appearances of the kidney when removed in November showed advanced tuberculosis.

In the Roentgen rays, again, we have a method that may guide us as to the condition of the opposite kidney in tuberculosis. A man, aged 37 years, under my care in Guy's Hospital, in 1906 complained of pain in the right kidney suggestive of calculus, supported by the presence of pus in the urine. There had been a history of pain in the left side some years before and it was possible that the kidney was destroyed. The x rays showed a large shadow on the left side only—i.e., the painless side—and the case suggested a reno-reflex pain. On opening this loin a hard calcareous mass was found, being the relic of a kidney shrunk to half its size. After dividing a thin and wasted ureter the relic of this kidney came away without ligaturing or dividing any vessels; they had completely atrophied. Unfortunately, a cystoscopic examination was not made. This man is now ill with tuberculosis of the remaining kidney. My experience is not sufficient to say how far the cystoscope would have guided the operative treatment in such a case. To be complete such an examination should have negatived all surgical interference, for the man suffered no inconvenience from the cretaceous kidney. The right-sided pain was due, no doubt, to tuberculous disease.

TREATMENT.

In reviewing the treatment of the cases referred to it will be seen that the kidney was removed in each instance. The appearance presented by the kidneys will, I think, be admitted to have fully justified the course adopted. Moreover, the speedy recovery of the patients, where the disease tuberculosis tends to lower the index. We have not found such a specific serum in lupus patients and this brings us to put the question, *Is there any such specificity at all?* or would the ratio between the two sera—normal or pathological—always work out like $\frac{1 \cdot 00}{1 \cdot 00}$ if they were counted with sufficient exactness?

2. As far as we know there does not exist any curve of immunity based on *daily* index estimations for one or more weeks before the first inoculation and *daily* index estimations after the beginning of the inoculation as long as this is continued. The reason why Sir A. E. Wright has not made such a curve is probably because his clinical material consists of out-patients attending a polyclinic; patients of this description, however, are not suitable for such examinations. This may also be the reason why he has not examined whether, and if so how much, the phagocytic power, when the curve is taken *in toto* (the "positive" and "negative" phases added), has risen. Commonly the authors of articles on the subject are content with speaking about the "positive" and "negative" phases.

We will now examine our material with regard to the question of the influence of T.R. on the curves *in toto* and we will use for this purpose the patients whose indices are shown in the accompanying curves. The arrows in the curves indicate the day of injection. We have always used new tuberculin (Koch) T.R. and the fractions indicate fractions of one milligramme T.R. The curves of the ten patients which we can use are the Curves 1–10.[11] In one case (Curve 1) the patient had received a single T.R. injection one and a half months before the first inoculation. Curve No. 11 (i.e., Case 1) cannot be used in this examination, as the indices of this patient were not determined before the first injection. We wish to state explicitly that none of these patients suffered from pulmonary tuberculosis. A glance at the accompanying curves and Table IV. will make it clear that the conditions in the individual cases are so different that it is necessary to treat the whole material summarily in order to get a decisive answer.

TABLE IV.

No.	Number of opsonic index before first inoculation.	Number of opsonic index after first inoculation.	Mean before first inoculation.	Mean error before first inoculation.	Mean after first inoculation.	Mean error after first inoculation.
1	7	34	0·97	0·14	1·01	0·24
2	16	80	1·03	0·28	1·01	0·24
3	15	79	0·99	0·26	1·03	0·24
4	16	76	1·05	0·30	1·16	0·29
5	16	79	1·25	0·48	1·21	0·30
6	16	84	1·17	0·31	1·04	0·24
7	16	23	1·12	0·27	1·20	0·25
8	16	12	0·93	0·18	1·17	0·34
9	8	75	1·00	0·16	1·03	0·21
10	10	9	0·84	0·33	0·96	0·32
11	0	44	—	—	1·01	0·23

We find then by looking at these curves before and after the first T.R injection that the mean opsonic index and the mean error are on the average 1·06 and 0·29 before the injection, whereas after the injection they are respectively 1·08 and 0·28. Apparently, no conclusion can be drawn from these figures. Still it must be taken into consideration that the mean opsonic index 1·06 is derived from only 136 observations and therefore is not so exact as the mean opsonic index 1·08 derived from 551 observations. Further, the result 1·06 dates from the first period where the exactness was the least, while 1·08 originates from the last three periods. If we now instead of 1·06 use 1·03, which we found above to be the mean of 408 indices from lupus patients not treated with T.R., the following question suggests itself: Is the difference between 1·03 and 1·08 so great that it can be correctly described as a rise? It can be calculated mathematically[12] that there is a probability of 995 against 5 that there is a rise.

Concerning the question of the "negative phase" a glance at the curves will show days on which the opsonic indices after injection of T.R are sometimes lower and sometimes higher than the index before the injection. No general rule is to be found. We are therefore obliged to treat also this question summarily, choosing from the curves such injections of T.R. as are made between two immediately consecutive index estimations. In other words, the indices which we use were determined on two consecutive days, and directly after the blood was taken for the first index estimation the T.R. injection was given. We have 36 such injections and we will now compare the sum of the 36 opsonic indices before the injection with the sum of the 36 opsonic indices after the injection, and get in this way an expression of the effect of T.R 24 hours after the T.R. injection.

The mean of 35 indices before injection = 1·08.
" " " after " = 0·99.

Mathematically, it can be calculated that the probability of a fall is 5 against 1, and with this probability our material then seems to prove the "negative phase."

3. We have seen that our examination may serve to prove the truth of Sir A. E. Wright's doctrine of the rise and fall after T.R. if we treat it summarily. On the other side, we must say that the index estimations have been of no help at all for the treatment of our patients. Where we have faced the individual case the effect of T.R. on the opsonic index has been so uncertain that the indices have been of no practical value to us at all.

When we now at last compare our result with those which we find in the literature at our disposal it will be seen that in important points we are of a different opinion. Bulloch found from 150 opsonic indices of 150 patients suffering from lupus a mean = 0·75. We found no difference between healthy persons and lupus patients. With regard to some of these 150 indices Bulloch found that cases with an index below 0·7 were not benefited by the Finsen treatment, while on the other side cases with an index higher than 0·9 were cured by the light treatment. We have divided our patients—as far as we have been able to judge the course of the disease—into two groups like the two just-named groups of Bulloch. In both groups we found an average index = 1·00. Bulloch and many with him think they may make use of one single index estimation and conclude from it with regard to the condition of the patients. Bulloch says that an index below 0·8 is rare or pathological. Many agree with him or put the limits at 0·7. But they do not pay any attention to the above-named law of error which asserts that it is not safe to draw any conclusion where there is not a difference greater than four times the mean error of the mean in the positive or the negative direction. This means that if Bulloch always worked with the same mean error (0·07) the limits would be 1·25 and 0·69—namely, 0·97 ± (4 × 0·07). Only outside these limits he is quite sure that an index is pathological. With regard to Lawson and Stewart, for instance, the limits would be 1·62 and 0·53—namely, 1·05 ± (4 × 0·13). This goes far to show that the one author is not allowed to use the limits of another. The same is the case with regard to the negative phase. When an observer before an injection finds the opsonic index = *a* and after the injection finds it = *b*, if *b* is smaller than *a*, most authors call it "negative phase" without asking if *b* is so much smaller than *a* that such a conclusion is legitimate. The case is exactly the same when the subject in question has a rise in the phagocytic power. As a rule the observer has estimated only one or two opsonic indices before the vaccination and still he speaks about rise without having proved that the indices before the injection—when these indices have been determined over a tolerably long period—are not exactly like the indices after the injection. It must be clearly understood that the necessity for taking the mean error into consideration is the more imperative in proportion as the greatest and smallest tuberculo-opsonic indices are very near 1. If we had met with indices that were from ten to 20[13] times the normal index one had perhaps been allowed

---

[11] These ten curves are shown under Cases 2, 3, 4, 5, 6, 8, 12, 13, 14, and 15. There is no systematic connexion between the numbering of the cases and the numbering of the curves. The number of each curve is in every instance shown in the right-hand bottom corner.

[12] Mr. Iversen, a mathematician, has calculated these figures and has kindly gone through the manuscript.

[13] In cerebro-spinal meningitis it is said (Miss Alice Taylor: THE LANCET, July 6th, 1907, p. 16) that indices = 40 (forty) are met with. If this is not caused by an agglutination of the bacterial emulsion by the serum the deviation from the normal (= 1) is here so enormous that a higher or lower degree of exactness is without any significance.

Feb. 20th, 1907, with a history of frequent micturition for five weeks, beginning quite suddenly with hæmaturia. He passed large quantities of blood for three weeks, and when admitted he had pain at the end of the penis and along the urethra, increased on micturition. Nothing was found on examination of the bladder by sound or cystoscope. The man at first passed urine every few minutes with great pain. There were some pus and albumin in the urine with tubercle bacilli. In three weeks with ordinary treatment the symptoms were much relieved and he could hold his urine for an hour. On March 15th he had the first injection of tuberculin and regularly attended under Dr. J. W. H. Eyre for this purpose as an out-patient. In six months this man had grown so stout and well as to be quite unrecognisable. All symptoms had long disappeared and the urine was free from pus and bacilli. I have no proof that this was renal tuberculosis but the clinical history suggests ulceration of the summit of a pyramid.

A routine examination of the urine for tubercle bacilli when small quantities of albumin and pus are found without renal or vesical symptoms, but associated with ill health and anæmia, will no doubt in the future discover many cases of early tuberculosis of the urinary tract. There can be little doubt that tubercle bacilli were present in Cases 1 and 2 long before the attacks of renal colic. The next point in the investigation of such a case is to discover if possible which kidney is affected by means of the cystoscope, or segregation, or other methods. The ureteric orifice will not exhibit characteristic changes till the ureter itself is affected. It may therefore be impossible to be quite sure which kidney is affected, as catheterism of the ureter is generally admitted to be dangerous in the presence of infection, and segregation is not completely to be relied upon. In the absence of localising evidence for treatment we must rely upon general methods and tuberculin injections, and it will be valuable in the future to know how far such treatment is successful. There seems no reason why renal tubercle taken early should not recover, and it is probable that among the cases of slight albuminuria treated on hygienic lines with good effect there have been instances of tuberculosis.

How long are we justified in waiting after tuberculosis has been localised in one kidney? That there is no necessity for immediate nephrectomy is shown by the cases recorded in the first lecture. The two complications—viz., infection of the bladder and of the other kidney on the one hand and dissemination of tubercle on the other—are certainly long delayed, and in many cases, extending over some years, never occur. Where, therefore, the tubercle bacilli are few in number, the albumin and pus variable and often small in amount, and where vesical irritation is quite bearable, the bladder healthy, and the ureteric orifice normal, postponement is justifiable, and how far complete recovery can be brought about under such conditions has yet to be ascertained. When the ureteric orifice shows positive evidence of disease operation should no longer be delayed.

Is the condition of the kidney any guide to expectant treatment? Roughly, there are two forms of renal tuberculosis: that where the products of destruction are retained, giving rise to a painless moveable tumour in the presence of good general health, and that where the products escape and the kidney, though somewhat enlarged, as in Case 3, may not be so clinically. In both the ureter is involved. In the first the bladder is less likely to be infected, though the vesical irritation may be quite as troublesome as in some of the second class.

These being the facts, which kidney gives the most favourable prognosis? An answer demands a more complete acquaintance with the later history of both classes of cases than we possess, especially of the second. The tumour cases, being so obvious, have been observed and spontaneous recovery, either by caseation or escape of the contents, is known to occur. So far as I know we must wait for the later history of the second group treated without operation. There is good reason for believing that cicatrisation of even extensive disease may occur, as in Case 2, leaving much of the kidney healthy. On the other hand, the danger of vesical and renal infection point to this variety causing more danger than that where the products are encysted.

Attention has been called to the well-established observation that both kidneys are rarely affected at the same time. Renal tuberculosis is in fact generally unilateral. The recognition of this distribution of the disease is of prime importance in considering surgical treatment, and therefore the means at our disposal for ascertaining the incidence of the disease become of the greatest moment. In a great many cases the clinical evidence is sufficient; there is pain on one side, as in Cases 1, 2, and 4. Again, there is, in addition, in the acute type, enlargement of one kidney. In Case 3 these signs were absent, and except for the newer methods of investigation operative treatment would have been delayed. It is beyond the scope of this lecture to enter into an examination of the value of segregation, cryoscopy, cystoscopy, &c. These questions have been recently discussed before the society, and it is sufficient to acknowledge the essential help afforded by cystoscopy in the management of these cases. Of the various methods this certainly seems the most reliable, but demands, like similar modes of investigation, constant practice, and most of us will have to rely for interpretation and guidance upon those specially skilled in the use of the cystoscope. It is easy enough to recognise gross changes and to see a calculus, but to pronounce from the appearance of the ureteric orifice one or other kidney in a sufficiently morbid state as to demand its removal requires more than a casual acquaintance with this mode of examination.

The diagnostic value of cystoscopy can hardly be exaggerated in renal and vesical tuberculosis. Without the information afforded by this method more than one operation referred to in these lectures would have been delayed or abandoned. The cystoscope, in fact, has become as essential in investigating diseases of the kidney and bladder as the ophthalmoscope in diseases of the fundus oculi and brain or the laryngoscope in diseases of the larynx. Though not the only method of determining the condition of the kidneys it seems to be the most satisfactory. When I look at my nephrectomies, in the "nineties," for instance, and even up to 1905, the routine practice was to ascertain by opening the abdomen the condition of the opposite kidney. Before I had decided for myself to put aside the abdominal route it was very convenient to explore through the incisions made for nephrectomy. When the loin route was decided upon it became my routine practice to make an opening through the opposite rectus and examine the kidney. In one instance bilateral cystic disease was found, only one kidney giving clinical evidence of enlargement. In another a horseshoe organ was found and operation abandoned in both. I do not mean that in every case such exploration was necessary. When, for instance, the kidney formed a large tumour containing pus, and clinically it was pretty clear that it secreted little or no urine, the abdominal exploration was dispensed with. When the cystoscopic examination cannot be made by an expert, abdominal exploration still remains the best means of obtaining the requisite knowledge. There are conditions, too, where the cystoscopic appearances must be doubtful, or even misleading, as in Case 4 reported in these lectures, where the ureteric orifice gave no indication that the kidney was tuberculous. Yet the ureter and kidney must have been diseased in October when the second examination was made, for the appearances of the kidney when removed in November showed advanced tuberculosis.

In the Roentgen rays, again, we have a method that may guide us as to the condition of the opposite kidney in tuberculosis. A man, aged 37 years, under my care in Guy's Hospital, in 1906 complained of pain in the right kidney suggestive of calculus, supported by the presence of pus in the urine. There had been a history of pain in the left side some years before and it was possible that the kidney was destroyed. The x rays showed a large shadow on the left side only—*i.e.*, the painless side—and the case suggested a reno-reflex pain. On opening this loin a hard calcareous mass was found, being the relic of a kidney shrunk to half its size. After dividing a thin and wasted ureter the relic of this kidney came away without ligaturing or dividing any vessels; they had completely atrophied. Unfortunately, a cystoscopic examination was not made. This man is now ill with tuberculosis of the remaining kidney. My experience is not sufficient to say how far the cystoscope would have guided the operative treatment in such a case. To be complete such an examination should have negatived all surgical interference, for the man suffered no inconvenience from the cretaceous kidney. The right-sided pain was due, no doubt, to tuberculous disease.

TREATMENT.

In reviewing the treatment of the cases referred to it will be seen that the kidney was removed in each instance. The appearance presented by the kidneys will, I think, be admitted to have fully justified the course adopted. Moreover, the speedy recovery of the patients, where the disease

MODERN METHODS OF TREATING INFECTIVE CONDITIONS OF THE THROAT.

BY MEREDITH YOUNG, M.D., C.M. EDIN., D.P.H., D.S.SC., &c.,
BARRISTER-AT-LAW; LATE MEDICAL SUPERINTENDENT, STOCKPORT CORPORATION HOSPITALS.

AS late medical superintendent of an infectious diseases hospital in which throat conditions of an infective or at least a bacterial character were of everyday occurrence I have for many years been exercised as to the best methods of combating such conditions, both from the curative and preventive points of view. Practice in this matter may be said to consist chiefly in the application of antiseptics by means of gargle, swab, spray, or douche, and practice varies in intensity from the squeamish use of a very mild gargle to the intrepid employment of a strong germicide under an anæsthetic. From both the preventive and curative points of view the annihilation, or at least the inhibition of growth, of the causal organism or organisms in such conditions is obviously the first thing at which to aim.

It is well known that what occurs in the case of true diphtheria bacilli during their growth on the fauces and throat—the formation, absorption, and circulation of toxic products—can also occur in the case of various staphylococci, streptococci, pneumococci, yeasts, and the like. We have not as yet for the latter conditions a mode of attack from within such as we have in the use of diphtheria antitoxin, except the use of antistreptococcic serum which I am of opinion is of decided value in many infective throat diseases. We are therefore compelled to rely upon methods which destroy the local toxin-factory or weaken its operatives so that their output is lessened. This is of especial importance in scarlet fever—a disease which I have long held to be strictly analogous to diphtheria in its pathology, there being a local bacterial factory in the throat from which toxin is distributed throughout the system to produce the secondary manifestations of the disease—lymphadenitis, nephritis, otitis, rheumatism, &c. It appeared to me, therefore, that as complete a test as possible, primarily bacteriological, of the value of the various antiseptics commonly used for the "disinfection" of the throat and of the various methods of applying these antiseptics would be of considerable interest. My first idea for the bacteriological test was to plant artificially some easily recognisable bacillus like the bacillus prodigiosus on the fauces and then to treat it with various solutions and note its diminution or disappearance. But on consulting Professor S. Delépine of the Public Health Laboratory, Manchester, whose kindness to anyone venturing on original investigation is notorious, I found that this had been tried with unsatisfactory results and that not the least objection to it was that it had at times resulted in unpleasant consequences to the subject. Obviously, as was pointed out to me, much more valuable results could be obtained by the observation of the behaviour of some bacterium actually growing on the throat than of some extraneous organism which might find the throat *per se* an undesirable residence. It was accordingly decided that I should endeavour first to find a throat which possessed fairly uniform bacterial contents and for this purpose I took swabs of a few throats for examination by Professor Delépine. The swab, which was of the kind ordinarily used in the diphtheria outfit at the health office, was rubbed gently first over one anterior pillar of the fauces and then over the other; it was then immediately labelled and sent off for examination, care being taken to send none at week-ends or during holidays when the delay would cause multiplication of organisms.

The method adopted by Professor Delépine for the examination of these swabs was to make an emulsion from each one in 5 cubic centimetres of sterile water, and from this to make a further dilution enabling agar plate cultures at 37° C. to be made containing $\frac{1}{5}$th, $\frac{1}{50}$th, $\frac{1}{500}$th, and $\frac{1}{5000}$th of the whole. The swabs were obtained under as nearly as possible similar conditions. They were not packed in ice to prevent or to lessen multiplication *in transitu*, but as all were sent in precisely the same manner the variations obtained are, I think, fairly attributable to the causes assigned. Care was taken to use the same amount of pressure on the mucosa when using the swabs, for any variation would naturally result in the swab picking up more or fewer bacteria in its journey. Some part of the variation in the results obtained is undoubtedly due to a difference in the amount of pressure employed, a matter naturally most difficult to control. Quantitative bacteriological work is at best an uncertain thing but the results obtained indicate that in these experiments the care taken in collection and examination has not been thrown away. Most of the colonies obtained were those of streptococci and not staphylococci as had been anticipated.

The first throats examined were those of three hospital nurses, in the first of which (Nurse G) I had a month previously excised a portion of one tonsil. All presented apparently normal fauces and the divergent results obtained are probably the consequence of the atmosphere to which they were exposed—that of a scarlet fever ward containing occasionally diphtheria, rhinorrhœa, otorrhœa, cervical abscesses, &c.—the usual accompaniments of scarlet fever.

	Swab No.	Staphylococcus.		Total colonies.
		Aureus.	Albus.	
Nurse G...	1	325	0	134,600
	2	75	165	1,320
	3	0	0	3,784
	4	0	25	97,000
Nurse M...	5*	0	2783	20,316
	6	0	25	966
	7	0	0	12,750
	8	0	616	10,330
Nurse E...	9†	—	—	—
	10	0	0	5,750
	11	0	0	59,250
	12	0	0	140,000

* Uvula accidentally swabbed in addition.
† Despatched wrongly and only examined for diphtheria bacilli.

These throats had to be abandoned for experimental purposes but the results are nevertheless interesting, if for nothing else at least for showing what a happy hunting-ground for microbic life the fauces are. It was accordingly decided to select a throat not so liable to accidental contamination. Swabs Nos. 13 to 17 were taken from the throat of an office clerk, aged 22 years, in good health and a non-smoker. The first three and the last were taken at 11 o'clock in the morning and No. 16 at 4 in the afternoon. In the case of the last named the tongue was very slightly touched with the swab, which probably accounts for the increased number of organisms present. Swab No. 17 was from one side of the fauces only. The results obtained were as follows:—

Swab No.	Staphylococcus aureus.	Staphylococcus albus.	Others.
13	0	0	300,000
14	0	0	200,000
15	0	0	430,000
16*	0	0	725,000
17†	0	0	64,250

* Tongue accidentally touched. † One side of fauces only.

Thus all the swabs contained a large number of organisms, and though there was considerable variation between them this was not so great as in the previous cases. Excluding Nos. 16 and 17 the average bacterial content of the swab was about 300,000. There was thus plenty of room for full appreciation of the diminution which it was anticipated would follow the application of antiseptics.

The organisms classed as "others" were streptococci which in the untreated throat were found along with the micrococcus tetragenus. After treatment the micrococcus tetragenus greatly predominated, showing that the streptococci were more easily eliminated by the reagents employed. It was accordingly decided to use this as the test-throat.

Gargling was the first method adopted and it may be remarked that the subject was an adept at this. After the use of the antiseptic the throat was invariably gargled once thoroughly with sterilised water, on Professor Delépine's advice, in order to prevent any of the antiseptic adhering to the swab and thus interfering with growth of the micro-organisms. A curious result was at once noted—namely, that after the use of the gargles staphylococcus albus frequently appeared and rarely staphylococcus aureus, although both of these had been absent prior to gargling. The only theory one could form to account for this was that the gargling process had forced the tissues and the bacteria attached to them out of their normal situation removed five months after incision and drainage, and yet complete recovery ensued. The time for nephrectomy has arrived when the general condition has improved and one is satisfied as to the adequacy of the opposite kidney.

Is it possible to excise a tuberculous focus if recognised sufficiently early? This, I believe, has been done, though I have no reference to the cases. In favour of this being accomplished I would refer to Case 1 as typical of the common site of early deposit—viz., in the lower pole, and to the obvious limitation of the disease for some time. Though the specimen shows extensive miliary infection of the lower third it is all fairly recent and suggests that had the condition been recognised at the time of the first attack of pain two years before, excision of the focus might have been carried out. A skiagram taken of this case three months before nephrectomy, showed an opacity in that part of the kidney where the focus was found, so that there is every reason to expect further guidance from this method of investigation. To be successful the ureter must, I expect, be free from infection, for though it recovers after nephrectomy it remains to be seen whether this will happen while urine continues to pass along the channel. The after treatment by tuberculin was carried out persistently in Case 1 from February to December, 1907, and was followed by complete disappearance of symptoms and of bacilli from the urine, and one may conclude by cure of the tuberculosis of the bladder and ureter. The opsonic index chart made by Dr. Eyre shows a persisting high index nearly all the time. In Case 3 tuberculin was not employed after the operation, partly because the ureter had been removed as well and partly because recovery progressed so satisfactorily. In Case 4 the unknown tuberculous kidney probably determined the failure of the tuberculin. The index in this case was often low. The treatment is still proceeding and the patient is gaining ground. There can be no doubt as to the value of this method of treatment, especially for vesical tuberculosis, and there seems no reason why it should not be valuable in early renal disease, especially when tubercle bacilli are found in the urine without vesical irritation. Where, as in miliary renal tuberculosis, the ureteric orifices are normal and there is no unilateral pain, it remains, together with hygienic measures, the only and best curative agent.

The object of these two lectures has been to review a personal experience in the light of the newer methods of diagnosis without going into the whole question or into statistics. To myself the importance of some of the early signs of tubercle has certainly only of late become recognised and I trust these lectures may be of service to others, especially those in general practice. I have related cases somewhat fully, giving at least all essential points in order that those who hear or read these lectures may be able to form their own opinions on the treatment adopted and on the suggestions put forward.

The early recognition of renal tuberculosis and the radical treatment by nephrectomy become of great importance, according as to whether it is held that such disease is recoverable or not. By recovery is meant cicatrisation of a focus, leaving the greater part of the kidney healthy; not disappearance of symptoms by total destruction of the kidney. The pathology of tubercle, especially as seen in the lung, would lead us to expect that spontaneous recovery of limited foci may take place. In the early stages there are no local symptoms of disease, nor in many cases is there ill-health. It is by the routine examination for bacilli in urine containing small amounts of pus and albumin that the earlier stages will be recognised. At this stage, when it may not be possible to localise the incidence of the infection by cystoscopic or other means, treatment by hygienic methods and by tuberculin hold out great prospects of success. As already mentioned I have little doubt that many cases of slight albuminuria, treated with success, have been examples of tubercle. There seems to be no reason why spontaneous cicatrisation of tuberculous lesions should not occur in the kidney as in other organs.

When, however, renal tuberculosis has advanced so far as to determine local symptoms, as pain, vesical irritation, a lumbar tumour, or gives rise to marked pyuria and albuminuria, is there any prospect of recovery with preservation of more or less healthy renal substance? I am not in a position to answer my own question, for the evidence from the post-mortem room is not in my possession, but I am inclined to think the information available is scanty, if existing at all. Perhaps this question may cause more attention to be paid to the subject and bring forward the pathological facts on which alone sound treatment can be based. In this connexion I would again refer to the specimen removed from Case 2. It exhibits cicatrisation in the lower pole of the kidney, the miliary infection being apparently quite recent. When local symptoms have developed the probability is that a progressive destruction of the kidney has set in and that no good will come of delay. That this destructive process may go on either steadily, with comparatively little general disturbance, or be interrupted by brief periods of acute illness, as in Case 1, seems no justification for a purely expectant treatment. If the outcome is to be a final destruction of the organ the rational treatment, it seems to me, is to cut short the illness by removal as soon as progressive disease has been recognised. To base a reason for delay upon the well-known unilateral character of the disease and the long resistance of the bladder and kidney to infection is to lose sight both of the fact that recovery means the final destruction of the kidney itself and of those cases where the spread of infection can be traced from one kidney to the other.

On every ground then early nephrectomy is indicated as soon as the destructive process has been localised and this may be on the first visit of a patient who has retained his weight and working power up to that moment. When a kidney shows so much healthy tissue as that removed from Case 1 a sense of regret at the sacrifice must be experienced. A close examination shows, however, wide miliary infection of the lower end, an amount of disease that could not be excised and would not have recovered spontaneously. Moreover, the ureter was tuberculous. The best guide to nephrectomy in the absence of a renal tumour or profuse pyuria is the cystoscope, and my experience teaches that when the ureteric orifice shows characteristic changes renal disease is beyond recovery and the sooner the organ is removed the better.

OBSERVATIONS ON THE OPSONINS, WITH SPECIAL REGARD TO LUPUS VULGARIS.

BY A. REYN,
OF THE FINSEN MEDICAL LIGHT INSTITUTE, COPENHAGEN;
AND
R. KJER-PETERSEN, M.D.,
ASSISTANT PHYSICIAN AT OERESUNDSHOSPITALET, COPENHAGEN.

PART I.

AMONG all the modern investigations on immunity perhaps no one deserves so much attention as Sir A. E. Wright's doctrine of opsonins. If this doctrine is shown to be correct every medical man who has a laboratory at his disposal will be in a much better position than before to treat many chronic infectious diseases against which the clinicians were previously more or less helpless.

Recognising the immense importance of this doctrine the Finsen Light Institute at Copenhagen decided to make the opsonic doctrine and especially the opsonins in cases of lupus vulgaris the object of a lengthy series of investigations. These investigations, which in our hands have not led to any practical result, are presented here, as we think that our experiences may form a link in the present investigations on the opsonins and their clinical value. We tried to find out if it were possible by tuberculin therapy guided by opsonic estimations to produce such an effect on patients suffering from lupus that the disease would either disappear or be relieved, light or x-rays being also sometimes used in the treatment. We divided the work between us in such a way that Dr. Reyn had charge of all the clinical investigations (examinations of the patients, injections of T.R., &c.), while Dr. Kjer-Petersen did all the laboratory work—namely, the estimation of the opsonic index.

I.—*The Opsonic Index.*

Before proceeding to the detailed account of our investigations we have to offer some criticisms on two assumptions which seem to be very important with regard to the opsonic doctrine. The first assumption is that phagocytosis is the most important or at least a very essential link in the resistance of the organism against infection. We know that each tablet is small and, in my opinion, the manufacturers have been well advised in proceeding on these lines. The pharmacist who crowds a large amount of antiseptic into one lozenge will not find his preparation appreciated, even if it be tolerated. Surely it is an easy matter to distribute the same amount in two or three lozenges and instruct the patient to take them more frequently.

The fact that the mouth, fauces, and pharynx are well supplied with muscles is frequently lost to sight, as is also the fact that certain very complicated movements are involved in the act of deglutition. A brief *résumé* of the processes of mastication and deglutition may not therefore be out of place here. Prior to actual swallowing—i.e., whilst the morsel is anterior to the isthmus of the fauces—it is turned over and over by the muscles of the lips, tongue, and cheeks, and is bandied about from one part to another of the oral cavity. The front of the tongue is then pressed against the back of the upper incisors, the back portion of the tongue is heaved up with a wave-like motion, and the now moistened bolus is carried, as it were, on the crest of the wave, through the isthmus of the fauces, the pillars of which first open apart to allow of its passage and then contract so as to partition off the buccal from the pharyngeal cavity. At the moment of "heaving" of the tongue certain other complicated actions take place by means of which the pharyngeal is shut off from the laryngeal channel. The constrictors of the pharynx immediately grasp the food morsel, the velum palati is elevated, and the orifices of the Eustachian tubes, which are probably closed during the resting or inactive condition of the pharynx, are now opened. The act of deglutition is finally completed by the passage of the morsel into the œsophagus and the onset of peristaltic action.

This semi-dissertation on the physiology of deglutition is not without important indications for treatment of buccal, faucial, and pharyngeal conditions. When the mouth is opened for douching, swabbing, or gargling, the parts, particularly the fauces, are at once thrown into an unnatural position, and many of these bacterial hiding-places are at the same instant covered up and protected from contact with the reagent applied. Moreover, the reagent can only be in contact with the parts to which it is applied for an inconsiderable period, and probably what little good results from such unnatural methods is effected by the reagent left on the parts mingling afterwards with the saliva and being carried in the manner just described to other parts. When lozenges or soluble tablets are used the mouth, fauces, &c., are not forced into any artificial position; the reagent dissolved in saliva and carried along by the muscular movements of deglutition flows for a considerable period over the surfaces to which it is desired to apply it; and what is of the greatest importance in diseases of these parts associated with the presence of bacteria the antiseptic is enabled by these muscular movements to follow the bacteria to their anatomical lairs.

I therefore wish to enter a strong plea for the elaboration of the lozenge treatment of mouth and throat diseases, to say nothing of other diseases where one wishes to give to a patient a drug to be taken, for example, during business hours, on journeys, &c. The dry concentrated form of drug meets many of these requirements and has many advantages, but it has this amongst other disadvantages, that the patient gulps it down whole (particularly if it be disagreeable) and it may lie for some time adhering to the stomach or intestinal wall where, if it be at all of an irritant nature, it is bound to produce discomfort and ill-effects on the mucosa. In the form of a palatable lozenge none of these bad effects need be feared. Further than this, I am a great believer in what physiologists term the "summation of stimuli" and I cannot help the thought that heroic drugging would seldom be necessary if some such means as the one suggested were adopted for the administration of frequent small doses of medicine. However, this is rather a digression.

Knowing the powerful germicidal effects of formaldehyde and observing the excellent results recorded of it by Dr. Daus[1] in acute follicular tonsillitis, mumps, acute submaxillary gland inflammation, and even in middle-ear disease, and the very good report of Dr. Piorkowski of the Bacteriological and Physiological Institute of Berlin, I determined to test these formamint tablets on the same lines as those on which gargles, &c., had been tested. I met with the most encouraging results. In a swab taken immediately after the sucking of one formamint tablet no bacteria whatever appeared, even in the dilution of one-fifth of the emulsion; in a swab taken ten minutes afterwards 35 micro-organisms grew, and in one taken 30 minutes afterwards 150 were present. There was, moreover, a total absence of staphylococci in all three swabs, the organism simulating the micrococcus tetragenus being the only one to resist the remedy and appearing in the two later swabs. This result is a little inconsistent with that obtained on swabbing with 1 in 200 formalin (*vide supra*) so that I repeated it in part with the following result. The patient's throat was first tested in order to get the bacterial contents of the anterior faucial pillars and the posterior pharyngeal wall. Next he was instructed to suck two formamint lozenges—one every half hour—and then to gargle with sterilised water. The fauces and pharynx were then examined and the results are shown in the following statement:—

Colonies Capable of Growth on Agar Plates at 37° C.

		Total colonies.	Staphylococcus albus.	Tetrads.	Streptococci.
1. Anterior Pillars	Before...	7500	0	900	8000
	After ...	80	45	0	15
2. Posterior Pharynx	Before...	965	650	0	200
	After ...	80	70	0	0

These results must be classed as distinctly excellent. I next proceeded to test two of the B.P. lozenges.

Swab C 1 was taken precisely as the other swabs, a few minutes after the slow sucking of trochisci eucalypti gummi, B.P., the throat being gargled immediately afterwards with sterilised water. The colonies yielded were: staphylococcus aureus, none; staphylococcus albus, none; total colonies, 6600.

Swab C 2 was taken after similar treatment with trochisci acidi carbolici B.P. and yielded: staphylococcus aureus, none; staphylococcus albus, 1500; total colonies, 41,000. The chief organism found was a tetracoccus closely resembling the micrococcus tetragenus.

The difference between these two lozenges is in my opinion due to the astringent action of the eucalyptus in closing up microscopic hiding-places for bacteria.

Clinical results.—These have been obtained chiefly in connexion with scarlet fever, diphtheria, "hospital throats," and the like. In no class of case is the hygiene of the mouth and throat of more importance than in scarlet fever. Left alone, many a case of this disease, simple at the onset, drifts into the septic variety; the organisms accompanying the specific one (whatever that may be) begin to flourish and invade accessory parts, setting up otorrhœa, rhinorrhœa, post-scarlatinal diphtheria, cervical lymphadenitis, &c. The most important line of treatment, therefore, in scarlet fever is, in my opinion, to keep the mouth and fauces in a condition unfavourable to the growth of these organisms. In the case of fauces already septic swabbing and douching are essential to remove the mucous and exudation which are almost always present. *It is useless to apply any curative until this has been done.*

In the septic or anginous variety of scarlet fever the tonsils and soft palate are œdematous and covered with mucous, and the condition is usually accompanied by ichorous nasal discharge. In such cases there are generally present some ulcers difficult to localise at first and most commonly situated in the angles between the uvula and palatal arches. Treatment is most difficult in these cases on account of the pain necessarily associated with it. But my experience has been that the best method is to begin with a very thorough cleansing of the parts, wrapping the child firmly in a blanket, using a mouth-gag if necessary, and swabbing first of all with some weak antiseptic such as 1 in 1600 hydrargyri perchloridum made up with a little glycerine and tinctura lavandulæ composita, then douching with the same solution, and afterwards putting the patient on to a liberal supply of formamint tablets. If the child can be encouraged to take these it will not be necessary to repeat the forcible swabbing and douching more than a very few times, and indeed the less it is done the better, for an ulcerated part cannot be expected to heal if we use measures that are bound to remove some, or perhaps all, of the newly formed epithelium which is growing over the ulcer. The swabbing, as the bacteriological examination already quoted shows, removes most of the presumably causative bacteria, and the mild antiseptic contained in the tablets

---

[1] Medizinische Klinik, 1906, No. 16.

It is seen from these two tables that we in the first period worked with a smaller exactness than later. Further, it is clear that there is no essential difference between the two sexes.

We wish now to see how these indices from healthy people correspond with the above-named law of error. In Table III. (where the number in the parentheses indicates the number calculated according to the law of error) we see the distribution.

TABLE III.

Within $\frac{1}{2}\mu$ ... (0·90–1·09): 268 = 39·8 per cent. (38·3 per cent.).
" 1μ ... (0·81–1·19): 489 = 72·4 " (68·3 ").
" 2μ ... (0·62–1·38): 643 = 95·5 " (95·4 ").
" 3μ ... (0·43–1·57): 669 = 99·4 " (99·7 ").
" 4μ ... (0·24–1·76): 673 = 100 " (99·994 ").

The nice correspondence is here evident and suggests that none of the observations have been influenced by a predominant cause, but only by the small individual causes which neutralise each other.

If we now inquire how the question about the exactness is answered by the different authors we at once meet with two difficulties. The one is that the authors never use this law of error already mentioned; the other is that they do not always state the exact arrangement of their investigations (for instance, whether they count 50 or more leucocytes, whether they use pooled serum or not, &c.). Many authors believe that Dr. William Bulloch[4] is right when he states that the tuberculo-opsonic index of healthy persons lies between 0·80 and 1·20. Even if this were correct it seems clear that not all observers are allowed to use the limits stated by Dr. Bulloch as limits to their own indices. The opsonic technique is a difficult one and *a priori* it is very unlikely that everybody at once can work with the same degree of exactness as Dr. Bulloch. In order that the determinations made by another observer may be of any value he must convince others, or at least himself, that he works with the same exactness as Dr. Bulloch. We also find in the literature of the subject the most different opinions with regard to the value of the opsonic index of persons in good health. Dr. Bulloch quotes Dr. R. H. Urwick—with what right we are going to see—as an author whose indices "correspond closely" with his own. In a paper by Potter[5] the indices of healthy people seem to be like those of Bulloch, but in a recent paper[6] Potter writes that the variations of the opsonic index are very great. W. Jensen[7] seems to believe that his own serum always has the index = 1. On the other side we find communications on higher indices. North[8] has found variations from 25 per cent. to 200 per cent. Dr. David Lawson and Dr. Ian S. Stewart[9] examining the blood of 25 healthy persons found opsonic indices of 1·40 in one person, 1·20 in five, 1·10 in five, 1·00 in seven, and 0·90 in seven.

It is clear that all examinations regarding the determinations of the indices of healthy persons (i.e., the estimation of the unity) in the hand of the individual observer must be made without the influence of any predominant cause (i.e., on a homogeneous material). We saw above that if an essential condition changed during the observations these would not become repetitions, and the numbers would not in that case correspond to the law of error. Such an example we have in Bulloch's series of 66 healthy indices. We find (the number in the parentheses indicating the number calculated according to the law of error)—

Within $\frac{1}{2}\mu$ ... ... 62·1 per cent. (38·3 per cent.).
" 1μ ... ... 80·3 " (68·3 ").
" 2μ ... ... 92·4 " (95·4 ").
" 3μ ... ... 100 " (99·9 ").

We see that Bulloch within $\frac{1}{2}\mu$ nearly has the double amount of the calculated (62·1 instead of 38·3). It is also very easy to understand by looking on his indices, where 26 (i.e., one-third of his whole material) have the value 1·00 in spite of the fact that between 0·80 and 1·20 there are 41 different values which the indices might have. In one way or the other a predominant change has been introduced in his experiments and therefore his indices lose their value as a basis for the estimation of the healthy index (i.e., the unity). Moreover, it seems strange that Bulloch never obtains indices higher than 1·20 or lower than 0·80. He uses his own serum as control. His serum must therefore on some day or other have an index = 0·80. If he now by chance on this particular day examined a normal person whose serum had the index = 1·20 this normal person's index would work out as $\frac{1\cdot 20}{0\cdot 80} = 1\cdot 50$.

We have seen above that in our 673 healthy persons we found a mean of 1·00 and a mean error = 0·19. It might be of interest to estimate the same figures for some other authors. Bulloch:—(34 healthy males) mean = 0·97, mean error = 0·07; (32 healthy females) mean = 0·97, mean error = 0·09. Urwick: (20 healthy persons) mean = 1·005, mean error = 0·11. Lawson and Stewart: (25 healthy persons) mean = 1·05, mean error = 0·13. Shaw: (seven healthy persons) mean = 0·98, mean error = 0·19. Bulloch seems, therefore, not to be justified in saying that he counts with the same exactness as Urwick; neither does the exactness of Lawson and Stewart seem to be exactly like Bulloch's. Our estimation of Dr. C. J. Shaw's mean error is only approximate, as he does not state all his indices. But as most of the authors have the same wrong view as to the way in which to state the exactness of their method it is worth while to quote him verbatim:[10]

> The average tuberculo-opsonic index of the six healthy control cases for five consecutive days was 1·07, the average for each case being 0·98, 0·97, 1·32, 1·06, 1·01, and 1·11, showing a variation between 0·97 and 1·32. This average index agrees with the results obtained by other observers in healthy persons.
>
> Urwick, in 20 cases, found the average index to be 1·006, while Bulloch in 84 cases found an index of 0·96, and in Lawson and Stewart's 25 cases the average was 1. The total variation 0·35 is less than that found by Bulloch in the 84 cases he examined. Urwick states that there is little variation in the index of a healthy person from day to day. I found considerable daily variations in some cases, though the observations were made as far as possible under the same conditions. The greatest amount of variation recorded between two consecutive observations was 0·3. In one control case, however, a record so low as 0·68 was obtained on one occasion.

The author just named uses the average (the mean) and the greatest variation as an indicator of his exactness, which, as we saw above, is quite wrong. Considering that this is the way in which most of the authors judge their exactness most people will agree that this fundamental question in the opsonic doctrine rests on a weak foundation. Until other authors determine their exactness in the same way in which we have done it (i.e., from a sufficiently great amount of material and taking regard to the law of error) it might perhaps be an open question if their fault is not as great as ours.

We now leave the opsonic indices of healthy persons and proceed to examine the indices of the lupus patients in the same way.

For the purpose of getting a general view we want to see what answer our material gives to the following questions. 1. How great is the tuberculo-opsonic index of lupus patients not treated with T.R.? 2. Does the treatment with T.R. produce a rise of the index curves *in toto* and a fall (the negative phase) after the individual injection? 3. Is it possible to use the indices as a guide to our treatment of lupus patients with T.R.?

Our material consists of 408 opsonic indices from adult lupus patients (23 males and 92 females) who either had not been treated with T.R. at all or at least had not yet had it at the time when these indices were determined. Some of these indices are to be found in the curves given in this article. We have also 551 opsonic indices from patients treated with T.R.; all these are to be found in the curves.

1. The 408 opsonic indices from lupus patients who have not had T.R. show a mean = 1·03 and a mean error = 0·25. The distribution is—

Within $\frac{1}{2}\mu$ ... (0·90–1·16): 177 = 43·4 per cent. (38·3 per cent.).
" 1μ ... (0·77–1·29): 298 = 73·0 " (68·3 ").
" μ ... (0·51–1·55): 393 = 96·3 " (95·5 ").
" 3μ ... (0·25–1·81): 405 = 99·3 " (99·7 ").
" 4μ ... (0·02–2·07): 407 = 99·8 " (99·9 ").

The typical distribution is not quite as good (too many cases within $\frac{1}{2}\mu$ and 1μ and 1 index outside 4μ) as in healthy persons, among whom we (as stated above) found a mean opsonic index = 1·00 and a mean error = 0·19, but still the figures go far enough to show that there is in our cases no essential difference between healthy persons and lupus patients. This is a very important fact as one of the chief points in Wright's theory is that the serum of tuberculous patients has a specific action, which in localised let nature complete the cure unaided. The continuance of those troublesome nasal discharges following on scarlet fever, diphtheria, measles, and the like is due in the majority of cases to improper prolongation of treatment.

ACQUIRED DIVERTICULA OF THE SIGMOID FLEXURE,

CONSIDERED ESPECIALLY IN RELATION TO SECONDARY PATHOLOGICAL PROCESSES AND THEIR CLINICAL SYMPTOMS.

BY W. H. MAXWELL TELLING, M.D., B.S. LOND., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE GENERAL INFIRMARY AND TO THE HOSPITAL FOR WOMEN AND CHILDREN AT LEEDS; CLINICAL LECTURER ON MEDICINE AND DEMONSTRATOR IN MEDICAL PATHOLOGY IN THE UNIVERSITY OF LEEDS.

(Concluded from page 850.)

CLINICAL ASPECTS.

THE clinical importance of these diverticula needs no further emphasis than that given by the number and gravity of the collected cases; yet it is only since Graser's communication in 1898 that the consequences of false diverticula of the sigmoid flexure have been seriously considered by the operating surgeon. But the time has come when no resourceful surgeon can afford to overlook the incidence of such cases; indeed, it is to the surgeon that we shall mainly look for an increase of our facts concerning them. It is by the "pathology of the living," as Moynihan happily phrases it, that we shall attain a proper clinical perspective with regard to them. One is almost constrained to think that we morbid anatomists have been a little slow in our appreciation of the pathological "possibilities" of acquired diverticula; certainly priority of observations rests almost entirely with our surgical colleagues. The foregoing pathological summary makes it scarcely necessary to attempt a detailed clinical differentiation of the various types of case; indeed, it would not be easy, for there would necessarily be much overlapping. But the great majority of the cases present themselves to the clinician in one of the four following ways, a few points concerning which yet remain to be mentioned.

1. *Inflammatory trouble, more or less acute, in the left lower abdomen (left-sided "appendicitis," sigmoiditis, peri-sigmoiditis, epiploic appendicitis, diverticulitis, peri-diverticulitis).*—Inflammatory cases of this type constitute a large and important group. Many of them are clinically identical with the various types of inflammation of the vermiform appendix (Nothnagel (54)[*]), except for the fact that the trouble is on the left side. So strong is the resemblance that in Bland-Sutton's case (No. 57) the question of transposition of viscera was carefully considered. Moreover, just as we are familiar with many cases of appendicitis which clear up entirely, there can be no doubt that this may happen in cases of "diverticulitis," and this latter, as we have seen, is very frequently indeed a true "epiploic" appendicitis. Such cases, coming neither to operation nor necropsy, are difficult to verify; yet a number of very suggestive ones have been put on record (Mayo (48), Patel (56), D'Arcy Power (14), and others). Moreover, the history of earlier inflammatory troubles noted in some of the cases proves the point. In the study of sigmoiditis (of which diverticula are becoming increasingly recognised as an important and frequent cause) the existence of cases which clear up is established beyond doubt (Tuffier (72)). Patel, indeed, says: "Peut-être un jour sera-t-on en droit de dire que, dans presque tous ces cas décrits sous le nom de sigmoidites, il s'agit de véritables *diverticulites*, absolument comme l'appendicite a été substitutée peu à peu à la typhlite." We may therefore hope to learn to recognise them as accurately, if not as frequently, as we do the analogous cases in the right iliac region. Georgi (21) emphasises the fact that in most cases there is at first marked inflammation of the diverticulum without symptoms. When these occur, the earliest are a little pain, aggravated by constipation, in the neighbourhood of the sigmoid flexure, and some sensitiveness to pressure; in marked cases a tumour is to be felt.

Left-sided tumour and abscess formation is a striking feature. In 63 cases a tumour was felt in 20 and abscess formation occurred in 23, though not in all cases giving rise to tumour, for the reasons given above. Georgi has further pointed out that with considerable pus formation there may be but little pain and no pyrexia.

In cases of sigmoiditis a characteristic tumour is often felt; it is elongated, sausage-shaped, tender, and often ill-defined; it may be moveable or fixed, lying a little above Poupart's ligament (frequently parallel with it). Shortly after the occurrence of abdominal symptoms referable (more or less definitely) to this quarter of the abdomen, this swelling may be made out: it may disappear, rapidly or gradually, or may increase, with signs of pus formation.

So far, the correct diagnosis of diverticular inflammation has apparently only once been suggested (by Mayo, Case 42). The suggestion would only be reasonable in a patient of middle age or older and who was the subject of marked or former constipation. Inflammatory trouble of the above kind occurring in such a patient would at the best render a diagnosis of *diverticulitis* very uncertain; it would be much easier to label a case *sigmoiditis*, one of the commonest causes of which is constipation (Capasso (8)).

The chief conditions to be considered in differential diagnosis would appear to be (*a*) ordinary appendicitis with left-sided symptoms; (*b*) pelvic inflammations; (*c*) ovarian cysts with strangulation or inflammation; (*d*) actinomycosis of the sigmoid flexure; and (*e*) syphilitic and tuberculous pericolitis. This list does not exhaust the possible sources of error; diagnoses of pancreatic, ovarian, and cæcal tumours have each been made. There seems to be a tendency to accept too readily tuberculosis as the cause of some of these non-malignant strictures of the sigmoid flexure; and F. S. Kidd (41), in discussing the differential diagnosis of these hyperplastic tuberculous cases, does not even mention the stenosis of diverticular origin.

2. *Intestinal obstruction.*—When acute this is probably due to secondary involvement of a coil of small intestine (Cases 59 and 50), and the initial cause is practically undiagnosable except at operation, where, however, its recognition may be of considerable importance. Chronic obstruction of the small intestine, of which my case, No. 51, is the only example, must also be similarly difficult as regards diagnosis. When obstruction occurs it is usually chronic, or recurrent, or acute upon chronic. It is generally localisable to the sigmoid region (to the ileo-cæcal in Case 80), and nearly always leads to a diagnosis of carcinoma. In the 25 cases in which there was stenosis of the bowel, in at least 12 the diagnosis of carcinoma was made, either before or at the operation; but in many the diagnosis is not mentioned. In England this mimicry of carcinoma has been referred to by Monsarrat (49), but Moynihan (51) alone has given it the emphasis which its importance deserves. The differential diagnosis from malignant disease is extremely difficult. Very advanced age, a comparatively recent constipation, marked cachexia and blood in the stools, all favour strongly the presence of carcinoma; while long-standing constipation, the absence (after repeated examinations) of blood from the stools, and slight cachexia together with any evidences of pus formation would suggest the possibility of a peri-diverticulitis; entire absence of constipation may occur with either condition, and blood has been found in the stools in at least one case of diverticular origin (No. 59). Many observers (Bland-Sutton (4), Gordinier and Sampson (22)) have no doubt that "cures" of cancer in this region have been due in some cases to the fact that the lesion has been one of simple inflammation and probably diverticular; Tuffier (42) quotes a very striking case. The proceedings may be greatly modified by a correct diagnosis at the time of operation. In some cases regarded as malignant further measures have been abandoned or a merely palliative operation (e.g., colotomy) performed, the amount of adhesion being regarded as a bar to more radical proceedings. These may, of course, be impossible whether the adhesions be due to simple inflammation or to malignant disease, but in one or two cases microscopic examination has revealed the absence of malignant disease and a radical operation has been then successfully carried out.

3. *Perforative peritonitis.*—Cases of this kind, in which the site of perforation is undiscoverable at the laparotomy, occur from time to time in the experience of every surgeon. It will scarcely be necessary to say now that a routine examination of the sigmoid region should always be made, with especial care if the age and previous history render the presence of diverticula in the least degree possible.

---

[*] The parenthetical figures throughout the article relate to the bibliography at the end.

to hope that the deviations were so far from the normal that these indices with certainty fell outside the range of errors, even if the mean error were a little greater or smaller. But now the tuberculo-opsonic index is very seldom twice as great or twice as small as the normal, that is to say, that the observations are so delicate that it seems hopeless to attempt to draw any inference without paying attention to the law of error.

To argue from our examination of the value of the tuberculo-opsonic index to the value of the index estimation might not be altogether fair, because the process of determining the tuberculo-opsonic index seems to be very difficult. Still, a great deal of the sources of errors quoted above keep their validity against other index estimations. And it seems to be a legitimate requirement that in the future this process must be worked with much more conformity of results and much more precision than has been the case hitherto.

A good deal would be gained if all investigators would agree to a systematic procedure the chief points of which for instance might be as follows: (1) the observer who counts a slide shall not be allowed to know to which patient the slide belongs; (2) in all cases the same number of leucocytes shall be counted; (3) the unit index shall always be determined in the same way—namely, by the use of pooled serum from at least six healthy persons and with 600 leucocytes counted; (4) the indices shall be determined to two places of decimals and the exact magnitude of the index shall be named even when the indices are exhibited as curves; (5) conclusions shall be drawn only from curves based on observations in which the indices before the vaccination were determined daily for one or two weeks; (6) the conclusions shall be drawn from a sufficiently great amount of material and shall be in conformity with the law of error; and (7) an opsonic immunity-curve corresponding to each individual bacterial type shall be made as an example. No systematic method of this kind has been adopted up to the present, but instead thereof we find scattered throughout opsonic literature a number of papers which are very incongruous in their foundation and in the value of their material. Until a programme like the one just proposed is generally adopted, and until we (when the investigators follow this programme) have got an undeniable proof of the reality of Sir A. E. Wright's doctrine of the opsonic index, we think it safer to dissuade practitioners from using these very troublesome determinations as a clinical method. We then would have more time to give Sir A. E. Wright's vaccinations a clinical trial to the extent which they require. The fact that a vaccination therapy is very seldom guided by daily index estimations seems to us a silent admission of the possibility of being able to vaccinate without determining the indices.

In concluding this section of our paper Dr. Kjer-Petersen wishes to express his most hearty thanks to Sir A. E. Wright and his assistants, who during Dr. Kjer-Petersen's stay at St. Mary's Hospital taught him the method of making opsonic estimations and most kindly spent much time in furthering the objects which he had in view.

II.—*About the Treatment of Lupus Vulgaris with T.R.*

In addition to these studies on the opsonic index we wish to communicate some cases of lupus vulgaris which we have treated by injection of T.R. according to Sir A. E. Wright's method. First we shall mention what we have been able to find in the literature about the results of this treatment.

Wright[14] publishes two histories of patients suffering from lupus vulgaris in whom great improvement was noticed after injections of T.R., and he furthermore relates that in several cases the results have been good, but he speaks only of one case of permanent cure. When the results have not been better Wright believes it is because the lupus is seated in a skin which is too poorly supplied with blood, so that that its anti-bacterial matters have not been able to act upon the tubercle bacilli. If a sufficiently pronounced hyperæmia of the skin can be provoked, such as is the case by the Finsen treatment, that method might, according to him, be of a much greater value. He therefore proposes to combine injections of T.R. with the Finsen treatment. If we had known these statements by Wright only we should hardly ever have tried the T.R. treatment as *sole treatment* against lupus vulgaris, but from other sides far better results of Wright's method have been related.

Bulloch[15] has, for instance, treated seven patients—all very old and extensive cases—who did not respond either to the treatment with x rays or to the Finsen treatment; four of these recovered, two were greatly improved, while one did not stand the injection with T.R. With regard to these histories we refer to THE LANCET, and we only wish to emphasise that the effect of the short treatment in Bulloch's four apparently cured cases has been astonishingly good. We are sorry to say that we have not been able to find in the literature any records of the later course of these cases which would have been of great interest, especially considering the short time of observation after the treatment and the pronounced tendency of some of the cases to relapse. Generally speaking, it is, in a disease like lupus, not too much to ask that the condition of the patients shall be followed through a longer time if the record is to be of any value.

Graham Little[16] relates one case where the patient's condition became worse, but he thinks that this was due to an overdose of tuberculin.

Butler Harris[17] has treated a very old case of lupus in which the patient quickly got better.

Turton and Parkin[18] relate two extensive cases of lupus which responded to tuberculin "much quicker" than might have been expected under any other treatment.

George Rose[19] has described the cases of two patients improved by Wright's method.

Ebert Hill[20] relates a case of lupus vulgaris of the upper lip which, after having been treated with different ointments, apparently recovered under the use of T.R. With the exception of this last-named case no author—as far as we have been able to discover—seems to have got so good results as Bulloch.

We will now proceed to mention the results which we have got, but at first we wish to go through the principles which we have followed in the treatment of our patients.

Wright recommends his method in such cases as have very low opsonic indices and do not react on, or always relapse after, some other treatment. But, as stated above, we did not find the opsonic index low in our lupus patients; on the contrary, their opsonic indices were, perhaps, just a little higher than in healthy persons. We were therefore compelled in choosing the cases to be guided by the result of earlier treatments, and to select such patients who, though energetic light treatment had been applied, either were not cured or even had become worse; we therefore selected eight of our most malignant cases (clinical histories 1–8 *infra*). As a contrast with these we tried the treatment in three small fresh cases (clinical histories 9–11 *infra*) which—as far as we could judge—would respond to the light treatment, so as to see whether the method, if it failed in the malignant cases, might perhaps be of value in the fresh cases.

Wright uses the opsonic index as a guide in the treatment. We have, as mentioned above, not been able to use the opsonic index for this purpose; we have used the doses and intervals which Wright indicates, and have injected quantities of $\frac{1}{1000}$ or $\frac{1}{5000}$ of a milligramme, increasing to $\frac{1}{500}$ of a milligramme. In a single case we have increased the dose to $\frac{1}{250}$ of a milligramme. The intervals between the injections have been about three weeks, which is the interval Wright uses, as far as we have been able to find out. Only in our first injections the intervals got more occasional as we tried if we could get any support by the opsonic index. We always used Koch's tuberculin (T.R.) sterilised at 60° C.

An account of a series of cases in which the method of treatment is given a full trial follows.

(To be concluded.)

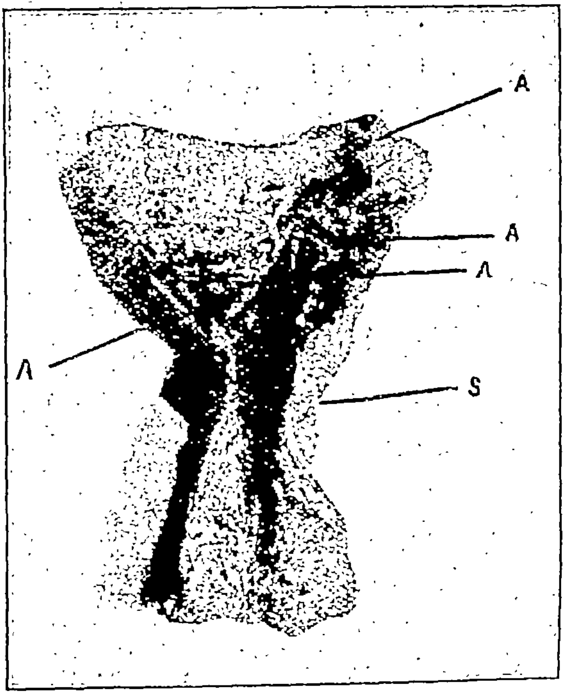
THE "E. M. I." (ETUDES MÉDICALES INTERNATIONALES).—The French railway companies have announced their intention of granting a new facility to the members of the Tour for Post-graduate Study which will be held in Italy from April 12th to 28th. The half-price return tickets to Nice will be available until May 15th in order to give their holders an opportunity of stopping on the Côte d'Azur. Moreover, the Paris-Lyons-Marseilles Company, with its wonted courtesy, will issue passes allowing the journey to be broken between Nice and Marseilles. Entries for the tour must be made before March 29th; communications should be addressed to the office of the "E. M. I.," 8, Rue François-Millet, Paris.

CASE 71 (Fabris (18), 1902).—Stenosis. Female, 68 years of age. Numerous diverticula of the sigmoid flexure extending up to nearly the middle of the transverse colon; they were from pea- to nut-size. In the rectum were chronic ulceration and stenosis, the fæcal obstruction due to which is looked upon as the cause of the diverticula. (*Note.*—Beer, who quotes the German abstract of this case, includes it under cases of stenosis of the gut *due to* the diverticula, whereas it is stated that the stenosis was regarded as the *cause* of the diverticula. I have not been able to look up the original reference.)

FIG. 3.



Specimen from Case 70. At S there is a narrow annular stricture of the sigmoid flexure from chronic inflammatory thickening of the gut wall. A A are the orifices of false diverticula. (There was probably much more thickening of the bowel at the site of stricture, but this inflammatory tissue has been "pared" away.)

CASE 72 (Ducos (15), 1906).—Stenosis; melæna. Aged female. Death from marasmus. Inflammatory stenosis of the sigmoid flexure for eight centimetres due to multiple diverticula at the site of the stenosis and above it; fæcal concretions in diverticula; melæna.

CASE 73 (Stierlin (68)).—Aged female. Multiple diverticula above a stenosing carcinoma of the sigmoid flexure. This case is interesting from its association with carcinoma.

CASE 74 (W. J. Mayo (48), 1905).—Stenosis; tumour (diagnosed as ovarian). Female, 62 years of age. Chronic constipation with attacks of pain in the lower abdomen for some time. Mass low down in the left side of the pelvis; diagnosis, ovarian tumour. At operation found to be the sigmoid flexure, eight inches of which were resected; thought to be carcinomatous. High-grade stenosis of sigmoid flexure due to a fat-containing inflammatory mass in subserosa round numerous thin-walled diverticula.

CASE 75 (W. J. Mayo, 1906).—Tumour, diagnosed as carcinoma. Male, 55 years of age. Flatulence for one year. A fortnight before there were pyrexia and abdominal pain, and a mass was found in the left iliac fossa. Here was tenderness and a mass, half original size, was felt. Resection of seven inches of the sigmoid flexure; thought to be carcinomatous. Chronic inflammation round multiple diverticula; one of these contained an enterolith. Numerous small "pocketings" of mucosa were also present.

CASE 76 (W. J. Mayo, 1902.)—Tumour; mesenteritis; diagnosis uncertain. Male, 41 years of age. Tumour and pain in the left lower abdomen for five months. Tender, hard, irregular, moveable mass felt in the sigmoid region. 16 centimetres of the sigmoid flexure resected; thought to be carcinomatous. Sigmoid mesentery contained a hard nodular mass—two diverticula with inflammatory exudate; the diverticula were much ulcerated.

CASE 77 (Gussenbauer (quoted by Beer) (1)).—Stenosis; tumour. Tumour in the left iliac fossa; diagnosis, carcinoma. At the operation stenosis of the sigmoid flexure with local peritonitis and abscess. Changes subsequently found to be due to multiple diverticula.

CASE 78 (Rotter (64), 1898).—Stenosis; submucous fistulæ. Male, 42 years old. Two months' constipation, three weeks urgent. Diagnosis: obstruction and peritonitis; colotomy; cause of obstruction not found.

Necropsy.—Fist-sized tumour of the sigmoid flexure, regarded as carcinoma but found to be due to inflammatory thickening from diverticula; there were fistulous tracts opening into gut. Mucosa otherwise intact.

CASE 79 (Rotter, 1897).—Stenosis; sigmo-ileic fistula. Male, 53 years of age. Symptoms of obstruction for six months. No previous constipation. Operation as for perityphlitis; artificial anus at end of ileum.

Necropsy.—In the upper rectum a stricture four centimetres long and three centimetres thick, allowing a lead pencil through. Mucosa healthy but above the stenosis was rugose with several fine openings leading to fistulous tracts; these were narrow and communicated with the lumen of the gut and with a small abscess cavity; this was adherent to the vermiform appendix and was in fistulous communication with loop of small gut. Condition regarded as secondary to a former appendical abscess.

CASE 80 (Rotter, 1899).—Tumour; abscess; stenosis. Diagnosis: carcinoma of the cæcum. Male, 58 years of age. Rumblings and pain in the cæcal region, with alternate diarrhœa and constipation for some time. Obstruction for nine days. In the ileo-cæcal region a large tumour of the size of a child's head; fixed, solid, irregular. Diagnosis: obstruction due to carcinoma of cæcum.

Operation.—The sigmoid flexure found to be adherent to the right side of the sacrum; ileo-sigmoid anastomosis. Tumour was formed by sigmoid flexure (20 centimetres) and its mesentery, in which is an abscess. Great thickening of gut with stenosis. Numerous diverticula; six enter abscess cavity.

General Peritonitis.

CASE 81 (Schreiber (69), 1902).—Male, 63 years of age. No previous history; obese; recent constipation; distended abdomen without definite evidence of peritonitis.

Necropsy.—Multiple diverticula of the sigmoid flexure (14), up to the size of a cherry; thin-walled, contained fæces. Bowel thickened and somewhat stenosed; rugose, partially concealing orifices of diverticula. One of the lowest had perforated and caused general peritonitis.

CASE 82 (Schreiber, 1902).—Male, 37 years of age. Stout; alcoholic. Six months' abdominal pain; loose stools.

Necropsy.—Mutiple diverticula (20) of the sigmoid flexure, in two vertical rows; one had perforated. Bowel somewhat thickened and mucosa of the sacs necrotic; contained fæcal concretions. Some fibrosis of the meso-sigmoid.

CASE 83 (Mertens (79)).—Male, 45 years of age. Eight days' pain in the lower abdomen, with constipation. As a result of straining at stool evidence of perforative peritonitis. Origin not located at the operation but at necropsy found to be due to a perforation of false diverticulum of the lower end of the sigmoid flexure.

CASE 84 (Warnecke (76), 1906).—Male, 42 years of age. Slight abdominal contusion; diffuse peritonitis. At the operation a perforation of a diverticulum at the junction of the sigmoid flexure and the rectum was found.

CASE 85 (Ruhwandl, quoted by Warnecke).—An old man with cancer of the tongue. Asthenic peritonitis from perforation of a diverticulum.

CASE 86 (Fiedler (19), 1868).—Female, 38 years of age. General perforative peritonitis; multiple diverticula.

CASE 87 (Pavlot, quoted by Patel (55)).—Female, 69 years of age. Several days' indefinite illness, not regarded as abdominal. General peritonitis; multiple diverticula of the sigmoid flexure containing fæcal concretions; two communicated with an abscess cavity which had burst into the peritoneal cavity.

CASES 88 and 89 (Pavlot, quoted by Patel).—Two cases of perforative peritonitis form sigmoid diverticula.

CASE 90 (Rolleston (62), 1905).—Female, 71 years of age. Old femoral hernia; abdominal symptoms, strangulation diagnosed; colotomy. Death in five days.

Necropsy.—Abscess round the descending colon, limited by loops of small intestine. Multiple diverticula of the sigmoid flexure. One had perforated and communicated with the abscess; general peritonitis.

CASE 91 (Hilbert, quoted by Georgi (21)).—Male, 37 years of age. Heart failure for six months. Suddenly symptoms of perforative peritonitis. Post mortem the peritonitis was found to be due to perforation of a sigmoid diverticulum.

CASE 92 (Brewer (6), 1902).—Gangrenous diverticulitis; abscess. Male, 45 years of age. Previously had had good health. Five days fever and pain in the left lower quadrant of the abdomen; here rigidity and a tender mass could be felt. Incision and draining of an abscess cavity which contained oblong fæcal concretions; there was a small ulceration in the wall of the sigmoid flexure.

CASES 93 and 94 (Brewer (6), 1904).—Epiploic inflammation. Inflammation of appendices epiploicæ due to infection conveyed from neighbouring false diverticula. The inflamed appendices were palpable as tumours (one of the size of a walnut and one of the size of a hen's egg) and were removed.

Vesico-colic Fistula.

CASE 95 (Sydney Jones (39), 1858).—Male, 64 years of age. Began to pass fæces and straw-like bodies in the urine for 10 months before death. At the necropsy the sigmoid flexure was somewhat contracted and presented a large number of diverticula of unequal length. One had ulcerated at its extremity and had given rise to an abscess outside the gut opening into the bladder; in this there was a fæcal calculus of the size of a horse-bean.

CASE 96 (Treves, quoted Mertens (79) and Heine (32)).—Similar case to above.

CASE 97 (Heine (32), 1904).—Female, 59 years of age. Constipated. Symptoms of vesico-intestinal fistula.

Operation.—Bladder strongly adherent to a hard tumour of the sigmoid flexure, taken for carcinoma. A piece was excised and the wound was closed. On examination the tumour was found to be inflammatory and to be due to peri-sigmoiditis around multiple diverticula. A subsequent radical operation was performed, with recovery.

CASE 98 (Hulke (38), 1859).—Male, 57 years of age. Symptoms of vesical calculus. Two and a half years before he had passed fæcal concretions per urethram.

Necropsy.—Stenosis of the sigmoid flexure from chronic inflammation round numerous diverticula. One had become adherent to and perforated the bladder.

CASE 99 (Morison (50)).—Male, 60 years of age. Stout. Three years symptoms of vesico-intestinal fistula.

Necropsy.—The sigmoid flexure was thickened and narrowed; at about the junction of the first and second parts of the rectum the gut was constricted by a narrow membranous band so that the lumen just admitted the tip of the little finger; stenosis of the gut in all three inches. Above and below this constriction were several "pits" in the mucous membrane; some were ulcerated at the extremity. A probe and the swab had picked the latter up in its journey round the anterior pillars. Swabs Nos. 18 to 20 show this markedly.

Swab No.	Antiseptic used.	Staphylococcus. Aureus.	Staphylococcus. Albus.	Others.
18	$HgCl_2$ 1 in 2000	0	125	675
19	HgI_2 1 in 2000	0	60	75
20	Cyllin 1 in 1000	0	90	102
21	Izal 1 in 800	0	16	45

These results were undoubtedly excellent as compared with those obtained from the normal throat and show the probable value of these now well-proved antiseptics; izal stands well out as a germicide but the subject complained of the pain caused by it. Amongst other antiseptics examined by the gargling process were the following:—

Swab No.	Antiseptic used.	Staphylococcus. Aureus.	Staphylococcus. Albus.	Others.
22	Boric acid, 1 in 40	—	250	12,750
23	Chinosol, 1 in 2000	—	5	375
24	Carbolic acid, 1 in 80	—	—	1,641
25	Lysol, 1 in 200	50	—	1,875
26	Distilled water	—	—	1,176
27	Lysoform, 1 in 200	—	—	445

There are no exceptional results here therefore except in the case of boric acid which certainly ought to stand condemned for this purpose. Lysoform and chinosol appear to be the best, but the former proved irritating; distilled water was found equal to most of the commonly advocated antiseptics. One is inclined to the conclusion that the action of a gargle is merely that of a mechanical flushing of the parts and with the exception of a few very strong germicides (Nos. 18 to 21) it appears not to be of much consequence what is used for the purpose.

Douching.—It is a curious thing that so few nurses know how to douche a throat properly. I always use now a wheeling table with two glass shelves and with an iron standard running up from one corner to support a syphon douche can containing the lotion to be used. A long rubber tube comes from this and is fitted with a pinch-cock; glass end-pieces are attached to the rubber tube and there are sufficient of these in a lotion bowl on one of the shelves to allow of thorough disinfection and cleansing. The child is wrapped firmly in a sheet, his arms being confined; the nurse sits the child up in bed and places her left arm round his neck so as to fix his head which is pressed against her left side. The head of the child is then bent forward over the receiving bowl. The nurse takes the tube with the pinch-cock in her right hand and passes the end-piece into the child's mouth *between his back teeth* (thus avoiding any interference by the tongue). The wrapping up of the child is a most essential part of the procedure, for it prevents struggling and thus prevents exhaustion, sometimes a vital consideration.

The only two substances tried were hydrargyri perchloridum 1 in 1500 (made up with a little glycerine and tinctura lavandulæ composita) and liquor calcis chlorinatæ 1 in 200, followed in each case by sterilised distilled water. The results are good as shown in this statement:—

	Staphylococcus. Aureus.	Staphylococcus. Albus.	Total colonies.
Hydrargyri perchloridum	25	—	60
Liquor calcis chlorinatæ	—	—	98

This method must therefore stand as *one* to be recommended for bacteriological cleansing of the fauces, but is hardly adapted for anything *except* hospital use on account of the difficulty of the operation and the dangers of it when improperly done.

Swabbing.—*Primâ facie* this would appear the most thorough way of bacteriologically cleansing the fauces as well as of insuring that remedial agents were closely applied. In practice I have found it of greater value than any other method. In order to obtain the best results the patient should be placed with the head well back over a pillow in pretty much the same position as for removal of adenoids so as to prevent any liquid expressed from the swab passing into the larynx. The swabs used should be nearly as large as a walnut and can conveniently be made of absorbent wool carefully fastened into an ordinary sponge-holder, or tightly twisted over a wooden holder with a roughened end and should be firmly and rapidly passed with a rotary motion not only over the fauces but if possible into the naso-pharynx, at least three or four swabs being used. Some nurses manage exceedingly well with a little lint wrapped over the forefinger, but this may result in a "poisoned wound" unless the nurse is extremely careful. The results obtained bacteriologically emphasise the value of this mode of treatment. Swab 03, taken after *gentle* swabbing with liquor calcis chlorinatæ 1 in 200, showed the following:—Staphylococcus aureus, none; staphylococcus albus, 10; total colonies, 75. The other organisms were the tetracoccus as before and some streptococci, yeasts, and sarcinæ, probably expressed from hiding places. After swabbing with 0·5 per cent. formalin there were only 30 colonies, all of the staphylococcus pyogenes albus, found capable of growth, an excellent result; the subject, however, did not care for the treatment, which he said was most irritating to the throat, nose, and eyes.

A very useful lotion in practice, inexpensive and unirritating, was one I had seen advocated for use for another purpose—namely, persistent otorrhœa—by a recent writer in one of the leading medical weeklies. Its composition is as follows: Acidum boricum, 1 ounce; spiritus vini rectificatus, 2½ ounces; glycerinum purum to 8 ounces. After swabbing the fauces once with this and then with sterilised water the bacterial flora of the anterior pillars were reduced to 25 total colonies and there was an entire absence of staphylococci and streptococci. I can therefore recommend this as a swabbing agent of very considerable value.

Antiseptic lozenges.—Pharmacy has certainly not developed this form of medicament to any degree of elegancy. The B.P. lozenges of the antiseptic variety—e.g., trochisci acidi carbolici and trochisci eucalypti gummi—may be tolerated by adults but children have to be literally forced to take them and adopt all kinds of tricks to get rid of them. Many adults are children in this respect. My own experience of them is that the children are to be commended rather than blamed for their discrimination. Trochisci potassii chloratis are slightly more palatable and tolerable but I have never experienced any good results with them. On one occasion when a patient used them very freely poisoning resulted. At one time I tried making lozenges of my own after the style of what I believe are termed "fondants," introducing a small percentage of antiseptic. For those who have sufficient time to devote to this form of pharmacy I submit the following recipe. Take one pound of icing sugar and the white of one egg; beat the egg till it is liquid; work the sugar into it; add the antiseptic; mix thoroughly and knead with the hand like dough; roll out into thin cylindrical masses; cut up into the requisite number of fondants, place on a plate, and allow to dry in the air. They do not keep well but have a tendency to go hard and lose efficiency in the case of volatile antiseptics.

The sole object of a medicinal lozenge is to keep the part of the mouth or throat one desires to treat bathed for a time in the drug dissolved in the saliva. The main point, therefore, to receive attention in the making of a medicinal lozenge is that it should be so temptingly constructed that children in particular will take pleasure in its consumption and therefore keep it in the mouth for a long time. I know of only one medicated lozenge—formamint tablets—which meets this requirement. My hospital children are not told they are to be given lozenges but that if they are good they shall have some "toffies"—a little dodge which works extremely well in practice. When they are subsequently given these formamint tablets they take them greedily and not infrequently actually cry for them. The only times at which any trouble at all has been experienced in their administration have been when there was acute tonsillitis or angina, and here of course the swallowing of anything at all is a painful process. Even in such cases, however, perseverance usually results in the taking of a few and then the painfulness disappears fairly rapidly and they are well taken. The introduction of a powerful and acrid drug like formic aldehyde into a palatable lozenge is certainly a pharmaceutical triumph. These tablets are stated to be a chemical combination of formic aldehyde with lactose in the proportion of 0·01 gramme of formaldehyde in 1 gramme of the total combination; citric acid and probably some flavouring agents are added. They evolve, *so it is stated*, nascent formic aldehyde in the mouth, and now and then one gets a slight burning sensation and the peculiar taste of this substance, though this is usually only noticeable with the first one taken. They produce a pleasing flow of saliva and the formaldehyde dissolved in this is carried by the process of sucking and swallowing to the various crypts and recesses of the mouth and throat. The amount of formaldehyde in covered. On opening the abdomen only the liver and stomach were to be seen. The liver, which weighed 11 ounces, was rotated upon a horizontal transverse axis—the upper and anterior surfaces presenting—and reached downwards to the symphysis pubis. The remaining part of the abdomen was occupied by the stomach. The stomach was much dilated, its walls were slightly thickened, and the pylorus especially was thicker and longer than usual. The left pleura was almost completely occupied by intestine, the lung lying in a collapsed condition at the apex. The whole of the intestinal canal between the third part of the duodenum and descending colon had passed through a hole in the posterior part of the diaphragm on the left side and occupied the left pleura, and passing out of this hole was the descending colon. There was no sac to the hernia. The herniated mass was easily reduced into the abdomen and along with it came the left kidney. The intestines were natural. There was no sign of strangulation. The heart was lying completely to the right of the left border of the sternum, the apex projecting to the right. The heart was otherwise normal. The right lung showed a little broncho-pneumonic consolidation at the lower lobe. The upper lobe was incompletely divided into two lobes. The opening in the diaphragm was about 3 by 2 inches—oval in shape. The edges were smooth and surrounded by muscle. The peritoneum was continuous with the left pleura over the margin of the opening. The spleen was in the abdomen and was natural, as was also the right kidney.

The occurrence of diaphragmatic herniæ is easily explained on reference to the manner of development of the diaphragm. Five elements enter into its formation: one median, two ventro-lateral, and two dorso-lateral. The median and ventro-lateral elements are first developed and together form the septum transversum. The two dorso-lateral elements are developed later and unite with the septum transversum to form the pleuro-peritoneal septum which shuts off the pleural from the peritoneal cavity. Hence the occurrence of diaphragmatic herniæ at the posterior part of the diaphragm, and owing to the manner in which the liver is developed they are much more common on the left side.

Two varieties of diaphragmatic herniæ have been described according to the period of development. 1. Embryonic type, which are formed before the complete closure of the pleuro-peritoneal septum, and therefore have no sac. These may be complete, when the whole of the dorso-lateral element is absent, or incomplete, when it is only partially absent. The above case was one of incomplete embryonic diaphragmatic hernia. 2. Congenital or fœtal: in these cases the pleural and peritoneal surfaces are formed but the muscular tissue of the diaphragm is imperfect. Hence in these cases there is a sac. A third type is "acquired," and is due to protrusion through an abnormally large normal orifice, such as that for the œsophagus.

Out of 481 cases collected by Paillard 80 per cent. were on the left side. Out of 130 cases observed by him 74 were complete embryonic diaphragmatic herniæ, of which only 18 occurred on the right side, and in 14 of these the liver was partially within the pleural cavity. In this case a diagnosis of pleural effusion on the left side was made but the sudden variation in the percussion note, which, according to Dr. Cautley, is due to the varying contents of the gut and the position of the liver, ought to have made one think of diaphragmatic hernia.

I am indebted to Dr. Cautley for permission to publish this case.

Note by DR. CAUTLEY.—A diagnosis of diaphragmatic hernia is rarely made during life because of the difficulty and largely because it is not suspected. In the present instance the dulness at the left base at first was ascribed to effusion and, as the amount of effusion assumed to be present could not have been large enough to account for, the position of the heart, transposition of that viscus was suggested. Subsequently the high-pitched resonance with absence of breath sounds and cardiac displacement could only be explained by diaphragmatic hernia. It was extraordinary how little distress the child suffered. In a case of diaphragmatic hernia on the right side under my care in 1905[1] there was great recession of the lower ribs and the child had many attacks of dyspnœa and cyanosis. In both instances exploration proved harmless. No doubt the intestines receded in front of the needle, for no evidence of puncture occurred at the time or was found after death.

[1] THE LANCET, Nov. 18th, 1905, p. 1472.

A CASE OF MERALGIA PARÆSTHETICA SUCCESSFULLY TREATED WITH THE CONSTANT CURRENT.

BY EDWARD REGINALD MORTON, M.D. TRIN. TOR., F.R.C.S. EDIN.,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT, LONDON HOSPITAL.

CASES of this condition are sufficiently rare to be placed on record, the more so because it is liable to crop up anywhere and at any time, and in the absence of any information regarding it an error in diagnosis is inevitable. Personally I was unacquainted with the existence of the disease until three years ago when I was consulted by a native Indian gentleman who had come to England for advice fearing he had contracted anæsthetic leprosy. He was a graduate of Cambridge and had a command of our language that might put many an English-speaking colonial to the blush, so that there was no difficulty in obtaining a very complete history of the case. I was, however, able to exclude everything I could think of that it might be, so I took him to see Dr. Henry Head, when I received my first introduction to this interesting condition.

For the benefit of those who are unacquainted with it I may say that meralgia paræsthetica is also known as Bernhardt's affection of the sensibility (*Sensibilitätsstörung*) and relates to the distribution of the external cutaneous nerve in the thigh. It is characterised by pain, numbness, a "dead or wooden feeling," or anæsthesia on the front and outer side of the thigh corresponding to this distribution. One of these symptoms generally predominates, the others being present in varying degrees or at different times. In some cases there is a feeling of tightness, as if there was insufficient skin to cover the part comfortably or that the part was bandaged. Probably the great predisposing cause to which all others are subservient is the superficial course of the nerve and the way it pierces the fascia lata. In occupations calling for extra tension on this fascia—the "hound-jog" in hunting, the blacksmith's hammerman, &c.—the nerve tends to become "nipped" at this point. In other cases trauma would seem to be the cause. It is also possible that the nerve sometimes passes in front of rather than behind the origin of the sartorius muscle, and is thus all the more exposed.

Morbid anatomy has given little assistance as to the pathology of the disease up to the present. Bramwell[1] mentions a case recorded by Nawratzki in which a spindle-shaped swelling about one centimetre in length was discovered on each external cutaneous nerve at the place where it crossed the anterior superior iliac spine. The microscope showed a localised perineuritis with associated interstitial and parenchymatous changes in the nerve. Those who desire to obtain more information than can be given here should refer to the paper by Bramwell which gives an excellent *résumé* of the literature up to 1903 as well as a very complete bibliography.

In my first case, above referred to, I could ascertain nothing in the way of a definite cause, while anæsthesia was the predominating symptom.

In the second case, a barrister, the cause appeared to be a swinging bar placed across one of the ways into Lincoln's Inn-fields, which he struck with the thigh as he passed through, and this happened the more frequently because of his very defective eyesight. Pain was the chief symptom here and was at times very distressing.

My third patient, a master of foxhounds, came to me on Nov. 7th last complaining of "lumbago," together with pain and numbness on the front and outer side of the left thigh. The pain was always worse after a day's hunting and seriously interfered with the night's rest. In between times numbness and a "wooden feeling" were the chief symptoms. On examination the "lumbago" turned out to be a dull pain in the sacral region, to which I attached no special importance and it entirely disappeared in a few days. The symptoms were first noticed about three weeks before. There was a slight tenderness on pressure just below the anterior superior iliac spine and the area of numbness and pain corresponded very accurately to the distribution of the external cutaneous nerve. That there was no definite disturbance of the various sensations of touch, pin-prick pressure, heat, and cold I attribute to the fact that I saw the case early and before any organic changes in the nerve had taken place. To mentioned may be relied upon to prevent their subsequent multiplication.

---

[1] Edinburgh Medical Journal, July, 1903.

Gegner[2] condemned the use of formic aldehyde as a gargle because of its irritating effects on mucous membranes, a fact well known to all who have used the substance. It is a fact that the use of formic aldehyde for swabbing, douching, or spraying the fauces causes the appearance of a bright red congestion in the mucosa and frequently in sensitive patients irritation of the nose and even of the eyes, accompanied by more or less watering. But after the use of formamint tablets I have had none of these signs of irritation and only very faint reddening of the buccal and faucial mucosa.

There was a fear that the use of formic aldehyde even in the very small amount present in a lozenge, such as that named, might increase the liability to albuminuria when used in scarlet fever, but the figures show that this is not at all the case. Out of 300 cases taken over a period of about two and a half years and treated without formamint 48 cases of albuminuria (i.e., 16 per cent.) were recorded of varying duration. Of 100 cases treated with the tablets given at the average rate of about 12 per day for about a week at a time only seven cases (or less than half the above rate) are recorded. Moreover, in several instances the tablets were continued throughout the whole of an attack of albuminuria and the albumin cleared up under suitable treatment during their administration.

It appears to me highly probable too that the employment of these tablets has prevented the development of septic conditions and their consequences. The following figures certainly seem to bear out this statement:—

Cases in which Formamint was not Used.

	No. of cases.	Percentage occurrence.
Number examined	300	—
Cases in which otorrhœa occurred	60	20·0
„ „ rhinorrhœa occurred	68	22·6
„ „ cervical lymphadenitis, &c., occurred	34	11·3
„ complicated by rheumatism	26	8·6

Cases in which Formamint was Used.

		Percentage occurrence.
Number examined	100	—
Cases in which otorrhœa occurred...	7	7
„ „ rhinorrhœa „	10	10
„ „ cervical lymphadenitis occurred	8	8
„ complicated by rheumatism	3	3

A few summarised records of cases of scarlet fever may serve to emphasise the utility of this form of medication.

CASE 1.—The patient, aged seven years, first became ill on Feb. 4th; rash on Feb. 6th; hospital Feb. 6th. Throat deeply congested; lacunar exudate on tonsils and fauces. Temperature, evening, 102·6° F. Formamint, one every hour. Feb. 7th: Temperature, morning 100·6°, evening 102°. Formamint as before. Feb. 8th: Temperature, morning 98·4°, evening 99°; throat perfectly normal. Uninterrupted recovery.

CASE 2.—The patient, aged seven years, first fell ill on Feb. 8th; rash on the 10th; hospital on the 11th. Temperature, evening, 101·8° F. Tonsils deeply congested and swollen; some doubtful pultaceous exudate left anterior fauces; thin, acrid, nasal discharge excoriating anterior nares and lips. Throat swabbed and douched with hydrarg. perchlor. 1 in 1500. Formamint one every hour. Feb. 12th: Diphtheria bacilli in nasal discharge and faucial swab. Congestion of tonsils, &c., lessened. Temperature, morning 101°, evening 101·4°. Formamint as before; no further swabbing. Feb. 13th: Temperature, morning 99·2°, evening 98·2°. Congestion quite gone; some exudate still adhering. Formamint one every two hours. Feb. 14th: temperature, morning 99°, evening 98·2°; throat normal. Slight rheumatism and albuminuria on Feb. 24th, readily cured. (N.B.—Antitoxin not given in this case.)

CASE 3.—The patient, aged three years, first fell ill on August 25th; rash on the 26th; removed to hospital on the 27th. Temperature, evening, 102·2° F. Fauces covered with wash-leathery membrane; slight nasal discharge. Antitoxin 6000 units; formamint one every hour. August 28th: temperature, morning 100·6°, evening 103·2°. Throat swab negative; nasal swab contained short diphtheria bacilli. Antitoxin 6000 units; formamint as before. Fauces still coated with exudate. August 29th: temperature, morning 100·2°, evening 99·4°. Fauces almost clear; nasal discharge much less. August 30th: temperature, morning 99·6°, evening 98°. Fauces quite clear; nasal discharge almost imperceptible. August 31st: temperature normal. *No diphtheria bacilli in three consecutive throat or nasal swabs.*

CASE 4.—The patient, aged seven years, first fell ill on July 13th; rash same day; hospital on the 14th. Temperature, evening, 103·4° F. Throat deeply injected throughout, tonsils considerably swollen, no exudate. Intense pain on swallowing. Formamint one every hour; badly taken at first, later with fair comfort; no other treatment. July 15th: temperature, morning 102·4°, evening 102·6°. Throat somewhat less congested; swallowing much easier. Formamint as before. July 16th: temperature, morning 100·4°, evening 99°. Throat quite normal; general condition excellent.

CASE 5.—The patient, aged six years, first fell ill on Dec. 22nd; rash on the 23rd; hospital on the 24th. A thin, poorly nourished child. Tongue soft, flabby, and crossed with deep sulci filled up with masses of dead epithelium; buccal and labial mucosa and gums soft, spongy, and containing numerous small greyish ulcers (scorbutic?). Temperature, evening, 102·8° F. Mouth swabbed out with glyc. boracis every four hours. Formamint tablets taken with difficulty: a few only. Dec. 25th: Temperature, morning 101·8°, evening 101·6°. Mouth and tongue somewhat cleaner but now appearing raw and beefy; very painful. Mouth swabbing stopped. Formamint taken rather better, about ten during day. Dec. 26th: Temperature, morning 101°, evening 100·6°. Ulcers on buccal mucosa disappeared. Tongue still very raw and painful. Dec. 27th: Formamint one every hour. Temperature normal. Gums and buccal mucosa firm and normal in colour. Sulci on tongue rapidly healing. Dec. 29th: Tongue, &c., perfectly normal except for thin bluish-white lines showing where sulci had been.

In one case of syphilitic ulceration of the tongue in a congenitally affected child, three years old, also suffering from scarlet fever, I had the best results from the use of formamint tablets, coupled, of course, with specific constitutional treatment. I have also had *temporary* benefit from their use in post-nasal follicular hypertrophy or adenoid growth; the nasal tone of voice and the mouth-breathing have both been improved for the time.

One cannot, of course, speak with certainty of the preventive properties of any drug, but a case which came under my daily observation may be cited as showing that in these formalin-containing tablets we have probably a useful prophylactic agent. A boy who had gone on a visit to a house developed pronounced mumps after being there a few days. There was no possibility of isolating him, and there were two other children of a susceptible age who had to share the same bedroom and come in pretty close contact with him all day long. I suggested that all three children should be given formamint tablets freely, and this was carried out with the result that despite their close contact the other children escaped the infection. This is only an isolated case, but it will certainly impel me to try the same experiment again. Mumps appears to me a disease for which this mode of treatment is peculiarly well adapted.

I hold no brief for this particular medicament, indeed, I think it one capable of considerable improvement, for the tablets dissolve too rapidly, and it would be better, in my opinion, if they were made more lasting—e.g., after the style of a jujube. The results obtained should stimulate pharmacists to the preparation of lozenges containing other antiseptics in a form such as will appeal to children and sensitive adults. Cases in which properly performed swabbing and douching have been successful are innumerable but I have none presenting special points of interest. The less sensitive the throat and therefore the longer the swab can be held firmly in contact with the affected part the more successful will be the treatment. In a very few cases I have applied *powders* either on dry swabs of cotton-wool or by insufflation to ulcerated fauces and tonsils. The chief difficulty is to find the exact site of the ulcer or ulcers, and it is sometimes quite impossible to locate them; in such a case it is useless to apply any powder on the off chance that you may cover the ulcerated patch. The most useful one for infective throat conditions is very finely powdered boric acid. Another for use in more severe cases is boric acid containing from ½ to 1 per cent. of lysoform. Powders must only be applied in very small amounts and with the greatest care to avoid possible irritation of the larynx.

The results then go to show that for throat disinfection *gargling* possesses no advantages, but, on the contrary, several serious disadvantages; that spraying is little better than gargling; and that the only reliable methods are swabbing and douching. Medication by antiseptic lozenges is an ideal line of treatment, in my opinion; it has been signally successful in my hands and I hope to see it considerably developed.

I cannot conclude without emphasising the necessity which my experience shows me is well recognised in hospitals but rarely is so in private practice—probably on account of the difficulty involved—of treating the post-nasal region as well as the fauces in almost all diseases of the throat and without exception in all infective conditions. The extra time and trouble necessitated will receive full repayment in the shape of much earlier cure. And my experience in such post-nasal conditions has led me to regard sulphate of zinc (one or two grains at most to the ounce) as one of the most useful remedies we possess. The nasal douching must be done in the *most gentle manner possible*; and when the condition is showing signs of abatement it is better to stop the douching altogether and to was considerably simpler and more rapid than the estimation of the opsonic value of the serum alone, which entailed washing normal cells and collecting blood in order to obtain both normal serum and the serum of the patient. It was merely necessary to draw up one volume of the patient's blood and one volume of a citrated salt suspension of the micro-organism to be used into the capillary tube, to mix, incubate for 20 minutes, spread the film, and compare the phagocytosis with that of one volume of normal blood similarly treated—a slight modification of the technique practised by Leishman. The only thing that would vitiate the estimate obtained by taking the hæmophagocytic as distinguished from the opsonic index would be evidence of an additional formation of opsonin *in vitro* during the 20 minutes in which the capillary tube containing the immune serum, the immune cells and melanin, or bacteria, was being incubated. That possibility Mr. Shattock and Mr. Dudgeon excluded by the following experiment: one volume of washed immune cells was thoroughly mixed with one volume of immune serum, having larger volumes than usual. The mixture was then drawn up into three capillary tubes of the usual calibre and incubated for 20 minutes, 30 minutes, and one hour. At the end of these intervals an equal volume of citrated salt suspension of living colon bacilli was added to the contents of each capillary tube, mixed, and each tube then incubated for 20 minutes. By that means a full supply of active immune cells were allowed to act in immune serum for different periods; the phagocytosis was then tested in each one after the same time allowance—viz., 20 minutes. The phagocytosis was the same in all. It might be held, thus, that the hæmophagocytic index, whether higher or lower than the opsonic, represented more accurately the blood resistance; if higher, that was not due to additional formation of opsonin in the drawn blood, and so fallacious, but to feeble activity on the part of the immune cells.—Sir A. E. WRIGHT said that the subject of the paper was not in a strict sense medical. The question whether opsonins were produced *in vitro* was remote from medicine. He considered that in discussing the avidity of white cells it was important that the number of white cells present should be stated, for without that fact the results could not be depended upon.—Mr. SHATTOCK, in his reply, said that he and Mr. Dudgeon considered that their communication had a very marked relation to medicine, because it concerned the estimation of the patient's resistance, and surely that was medicine. In the pneumonia cases which they had brought forward the height of the indices marked the fact that the white cells were doing more work than normal cells. In regard to the number of white cells it must be remembered that in blood taken from a case of pneumonia the number of leucocytes was greater than in normal blood.

---

[2] Münchener Medizinische Wochenschrift, 1893, p. 699.

Dr. ARTHUR LATHAM, in conjunction with Dr. H. R. D. SPITTA and Dr. A. C. INMAN, communicated a preliminary note on the administration of Tuberculin (T.R.) and other Vaccines by the Mouth, together with (*a*) normal saline solution, and (*b*) fresh horse serum. They stated that the treatment of disease due to bacterial invasion by vaccines gave brilliantly successful results in many cases. The hypodermic injection of Koch's tuberculin in pulmonary tuberculosis not only increased the percentage of arrested cases in those undergoing sanatorium treatment but diminished the tendency to relapse. The use of tuberculin and other vaccines on a large scale had been attended with great difficulty owing to (1) the fact that the hypodermic method of administration had to be employed; and (2) the necessity in most instances of making frequent estimations of the opsonic index in order to determine the proper intervals between the doses. One of the objects of the investigation was the simplification of their present methods. On the assumption that immunity against certain diseases was often due to the absorption of the products of dead micro organisms from the alimentary canal, it was decided to try the effect of administering various vaccines by the mouth. In the treatment of disease of bacterial origin the production of antibodies which had a direct effect on the specific poison was not always sufficient. The opsonic index might be raised but the progress of the disease might continue unabated. In other cases there might be no response to vaccination. Again, in tuberculosis the fact that the destruction of tissue varied immensely in different cases suggested that something besides the direct effect of tuberculin had to be considered. Those facts might be due to some deficiency in the patient's serum. There was a considerable amount of clinical evidence of the value of various antisera, such as antidiphtheritic serum, in diseases other than the specific disease. It was probable that some of those effects were due to the action of horse serum. There was also evidence of the value of horse serum in hæmorrhagic conditions of toxic origin and certain other conditions, whether administered by the skin, mouth, or rectum. Fresh horse serum was therefore given in a number of cases in order to determine whether it was able to supply some substance in which a patient's serum was deficient, or to stimulate the production of some such substance, or whether it had any other action. The investigation was commenced at St. George's Hospital. The treatment was carried out on purely clinical considerations; at the same time, Dr. Spitta made daily observations of the opsonic index in a number of the cases. At the end of three months, a considerable amount of information having been obtained, patients were also treated at the Brompton Hospital for Consumption. At that hospital the patients were seen daily in consultation with Dr. Inman, who made a large number of observations of the opsonic index. The cases treated embraced cases of advanced pulmonary tuberculosis, tuberculous peritonitis, tuberculous disease of the glands and hip, and cases of streptococcic, staphylococcic, and pneumococcic infection. Evidence, clinical and bacteriological, was brought forward to show that—(1) satisfactory immunisation could be produced by the administration of vaccines by the mouth; (2) in tuberculosis and other diseases of bacterial origin in which fever was present there was a definite relation between the curve of the opsonic index and the temperature, and that the more frequently the index was determined the more definite was that relation; (3) in such diseases the temperature, even when normal or subnormal, afforded some guide to the changes of phase in the opsonic index; and (4) horse serum in certain cases had an effect on the opsonic content of the blood.—Dr. F. W. FORBES-ROSS described certain investigations which he had carried out and published in the *New York Medical Journal* of Nov. 9th, 1907.—The discussion was then adjourned.

PATHOLOGICAL SECTION.

Larvæ of Eristalis Tenax Passed by the Bowel.—Enlargement of Hen's Comb Produced by Injections of Testicle Extract. —The Relations of Endothelioma to other Forms of New Growth.—Prickle Cells in Tumours.

A MEETING of this section was held on March 17th, Mr. S. G. SHATTOCK, the President, being in the chair.

The PRESIDENT read a paper on the Larvæ of Eristalis Tenax passed by the Bowel. He exhibited some that were passed with many more, in the living state, by a woman who had recently arrived from France where she had eaten much watercress. The larvæ were identified by Mr. E. E. Austen as those of the dipterous fly, *Eristalis tenax*. The larvæ, which were as large as tadpoles, were furnished with a respiratory proboscis or "tail," and were commonly known as "rat-tailed" larvæ. Oviposition took place upon material at the surface or edge of water, and the ova (about one millimetre in length) had presumably been ingested concealed in watercress. As one of the habitats of the larvæ was sewers there was nothing incongruous in their development in the intestinal contents. The oxygen for respiration during their development in the intestinal canal would be provided by the air swallowed. A considerable number of cases of intestinal myiasis had been recorded, but the larvæ passed were usually those of different species of homalomyie. No example of eristalis had been before observed in this country and only two or three cases had been placed on record abroad. The fly itself closely resembled an ordinary drone and entomologists had pointed this out as the explanation of the ancient method of raising "bees" from the decomposing carcass of an ox, described by Virgil in the fourth book of Georgics.

Mr. C. E. WALKER communicated a paper on the Influence of the Testis on the Secondary Sexual Characters in Fowls He referred to the previous work bearing upon this subject carried out by Shattock and Seligmann and pointed out that the object of the experiments which he (Mr. Walker) described was to ascertain whether certain groups of cells in fowls of both sexes possessed the potentiality of developing in a particular way under a suitable stimulus. This stimulus, he claimed, was shown by his experiments to be supplied by the

4. *Vesico-colic fistula.*—These cases form a well-defined clinical group with an interest similar to that which attaches to the bowel stenosis cases, in that the diagnosis of carcinoma may be made during life and even at necropsy. There is a further point of resemblance: just as the bowel stenosis cases have only recently (1898) had their origin clearly defined and numerous cases prior to that date have certainly been overlooked, so it is only beginning to be recognised that vesico-intestinal fistulæ also have this origin not very infrequently. It is true that a very clear description of the condition was given by Sydney Jones (Case 95) as early as 1858, *but subsequent* writers have failed to attach sufficient importance to acquired diverticula being the original cause of adhesion between the bladder and the sigmoid flexure or the large bowel in its neighbourhood. Harrison Cripps (12) in his monograph on "The Passage of Air and Fæces through the Urethra" (1888), includes Jones's case but makes no comment on its peculiar pathology. Heine (32) in 1904 carefully investigated the recorded cases of the kind and collected seven of undoubted diverticular origin and nine more in which such an origin was extremely probable. Moynihan (51) has recently drawn attention strongly to the clinical importance of this cause: he says "the formation of a vesico-intestinal fistula seems to be one of the tendencies of a perforated false diverticulum; a search through the literature has shown that it is far more common than was *supposed*. In cases where a hard growth in the intestine is accompanied by the passage of flatus and fæces by the urethra, a diagnosis of carcinoma seems *irresistible*, yet the *probability* is that 'the growth' would be simple, and that the cause of the fistula would be a false diverticulum which had burrowed its way through all the coats of the bowel, and thence through the wall of the bladder which had become adherent." The italics are my own: perhaps many would think the substitution of "possibility" for "probability" would be more accurate. Yet the evidence does not support this. It is a common belief that the most frequent cause of vesico-intestinal fistula is malignant disease, but this is not so. Cripps clearly demonstrated this; in 63 collected cases he found the fistulæ to be as *follows*: traumatic, 2; cancerous, 9; inflammatory, 45; and unascertained, 7. It may be argued that if cancer be a common cause *cases collected from* the literature will show an undue proportion of inflammatory ones as being more noteworthy. Cripps does not take this view, as four of his *cancerous* specimens were museum ones; from this he thinks there is a disproportion in favour of cancer, owing to its *necessarily* fatal character and the ease with which specimens are thereby collected in museums. The more recent statistics of Chavannaz (10) support these conclusions; he *puts* the cases due to malignant diseases at almost 20 per cent. Indeed, the tendency of cancer of the bowel to cause this fistulous *communication by direct extension* of the growth has probably been much exaggerated; Kelly and McCallum (40) point out that the fistula is more often *above* the growth and not directly due to it; cases of the latter kind they estimate at less than 10 per cent. of the whole. In Cripps's 63 cases the situation of the fistula was—

Rectum	25	cases.
Colon { sigmoid flexure 11 not stated 4 }	15	,,
Small intestine	12	,,
Colon and small intestine	5	,,
Unascertained	6	,,

Chavannaz finds that in 95 cases 24 per cent. were between the bladder and the sigmoid flexure. These figures tend to disprove the frequency of cancerous fistulæ, but they do not directly prove their origin to be *diverticular*, as distinguished from other causes of inflammation. But Heine's research helps strongly in this direction; the study of his nine probable cases will convince one of this. My own observations support his conclusions; Cases 52 and 99 are "missed" cases (in the latter the pathology was unrecognised by the author and by at least one subsequent commentator). On museum shelves I have found specimens which are almost certainly of this nature, but, of course, one must handle them actually to verify this.

One is anxious to avoid drawing stronger conclusions than the facts warrant, but there can be no doubt that vesico-sigmoid fistula due to acquired diverticula of the bowel is a definite pathological condition of some frequency. The practical importance of these facts is considerable; they hold out a much greater prospect of relief by surgical interference. An operation may be either merely palliative or as a preliminary to more radical measures; in either case left colotomy will be the most probable proceeding; or a radical operation may be undertaken in the first instance.

The liability to post-operative peritonitis.—In several of the cases general peritonitis has followed operation. Though no positive conclusions can be drawn from the small number of cases it is possible that the cause is not *necessarily* infection from without at the time of operation. In all the cases we have a possible source of sepsis in the thin-walled sacs *with their fæcal contents: there is certainly, therefore,* an added risk in the operation. The practical hint would seem to be that every case of supposed carcinoma, or other stricture in this neighbourhood should be examined with scrupulous care, and if there be any possibility of a diverticular origin the question of the advisability of a modification of the toilette of the operation should be considered.

I append a summary of the cases other than those given in the text, which I have been able to collect. I have no doubt that the number will be enormously increased in the next few years, and our knowledge will become more precise in consequence.

In conclusion, I have to thank many of my colleagues at Leeds for the help they have afforded me, both by material and suggestions; especially must I mention Dr. J. Kay Jamieson, Dr. G. W. Watson, and Dr. James Allan. My thanks are also due to Dr. J. Fawcett, the curator of Guy's Hospital Museum, several specimens from which I have included in the above text and summary.

*CASE 64 (Guy's Hospital Museum, Preparation 2522).—Stenosis, abscess. Entry in catalogue: "Portion of colon of which the canal is at one part nearly closed by thickening and contraction of its walls. At seat of stricture mucous membrane is raised into thick folds and several ulcers lead through it to narrow fistulous canals which pass into the surrounding condensed tissue in the course indicated by some bristles. *It is probable that this disease originated in an abscess in the cellular tissue connecting the colon with the abdominal walls.*" The stricture is at the lowest part of the sigmoid flexure; the "ulcers" are undoubtedly the orifices of diverticula, with smooth edges lined by mucous membrane.

CASE 65 (*Guy's Hospital Museum, Preparation 722, Dr. Prance, 1836*).—Abscess. Male, 60 years of age. Constipation and abdominal pain for ten years. Abscess in the left side of the abdomen six weeks before death. *Necropsy: emphysema, enlarged heart.* Abscess cavity between the left kidney and the colon which communicated with the bowel through an aperture at the bottom of the specimen. This is undoubtedly the *sigmoid* colon; *it is much sacculated*, and the sacculations involve the normal haustra. In the floor of these, as well as in other situations in the mucous membrane, are smaller orifices leading into *tubular* passages which are lined with mucous membrane. These for the most part doubtless entered the fatty tissues of the appendices epiploicæ, but this is now carefully cleaned away, showing many of the diverticula cut across. "At the bottom of the *preparation one of* the sacculi shows a small perforation, through the edges of which the mucous membrane is everted" (catalogue). This is probably the specimen referred to by Hale White (27).

CASE 66 (Penrose, quoted by Rolleston (62)).—Retroperitoneal abscess diagnosed as pancreatic tumour. Female, 47 years of age. Abdominal tenderness and pain, flatulence and sickness for 18 months; worse one month. Tumour in the left side thought to be connected with the pancreas; found to be due to large retroperitoneal abscess, extending from the brim of the pelvis to the diaphragm. At the lower end of the descending colon three ulcers (one at the tip of a diverticulum); two opened into the abscess.

CASE 67 (Fiedler (19), 1865).—Abscess perforating externally. Female, 64 years of age. Former constipation; last *few* years loose stools; obese. In the left iliac fossa a tender, irregular tumour; the overlying skin somewhat œdematous and infiltrated; considerable pyrexia. Abscess burst by fistulous openings in abdominal wall and fæcal material was discharged; an abscess formed subsequently in right iliac region.

CASE 68 (Fielder, 1868).—Abscesses. Female, aged 22 years. Nutrition good; chronic constipation. Abdominal pain, distension, and tenderness; maximal in the sigmoid region; diarrhœa. Large abscess in left iliac region extending *to* the right of the pelvis; numerous perforations due to diverticula, leading from the colon and especially from the sigmoid flexure. Some only ulcerated and contained fæcal masses. Adhesion to neighbouring coils.

CASE 69 (Bigg (2), 1904).—Extraperitoneal abscess. Multiple diverticula of the sigmoid flexure; one had perforated and had caused an extraperitoneal abscess.

*CASE 70 (Museum of Leeds Medical School, Preparation E216).—Stricture of bowel. No history or notes (old specimen). Narrow, annular stricture of the sigmoid flexure seven inches from the anus; it barely admits a lead-pencil and is caused by inflammatory tissue only. Much of this has been carefully pared away; in cleaning away the appendices epiploicæ and fat from the rest of the gut several diverticula are seen to be cut across. The mucosa at the point of stricture is superficially ulcerated; above this it is normal and presents false diverticula in two rows on either side of the meso-sigmoid. On one side there are five such; three of these are cut across. On the other side there are three shallow pits which are early diverticula somewhat stretched out by the dilatation of the gut above the stenosis. In the strictured area is a "pouch" but owing to the ulceration and to the paring away of the inflammatory tissue outside the stricture this cannot certainly be identified as a diverticulum, though it probably is of this nature invariably underwent flattening and softening (*assouplissement*) and were gradually or suddenly displaced out of the pelvis, sometimes as late as the onset of labour itself, and labour spontaneously occurred without assistance.—Dr. T. W. Eden agreed with the previous speakers as to the rarity with which serious complications occurred when women with fibroids became pregnant and deprecated the view sometimes advanced that pregnant women with fibroids necessarily went in peril of their lives.- Dr. A. E. Giles said that speaking in generalities would lead to confusion and inaccuracy. To say that the complication of fibroids and pregnancy was generally unimportant was as much beside the mark as to say that it was generally dangerous. The existence of fundal fibroids might make no difference to pregnancy or labour but cervical fibroids impacted in the pelvis were in a totally different category. He alluded to a case in which he had removed a fibroid from the left broad ligament in a woman four and a half months pregnant. He experienced great difficulty in stopping the bleeding and though he succeeded at the time it recurred later, necessitating the removal of the uterus, as in Dr. Dauber's case.

A short communication was made by Dr. H. Russell Andrews and Dr. R. Drummond Maxwell on a case of Difficult Labour, with remarks on the frozen sections of the uterus. The patient had been in labour for two and a half days before the resident accoucheur was sent for. He found a very large decomposing child presenting by the vertex. Attempts at craniotomy and cephalotripsy resulted in the whole of the head being pulled off and traction on the arms pulled both of them off. An attempt at version failed, the foot coming away without any alteration of position being effected. The patient was then sent into the London Hospital. When Dr. Andrews saw her the uterus was in a state of tonic contraction. He cut through both clavicles, perforated the chest, and removed the heart and lungs, perforated the diaphragm, and removed the liver and intestines. In spite of effecting diminution of the size of the child no form of traction applied by every conceivable variety of hook and forceps was successful and attempts at version met with no more success. It was impossible to cut through the fœtal spine. At last, after one and a half hours' hard work, realising that he could not deliver per vaginam, he removed the uterus with the child *in situ*, preferring hysterectomy to leaving the patient undelivered with the uterus in a state of tonic contraction. The patient died on the next day. The child, who had apparently reached the age of 44 weeks, must have weighed not less than 13 pounds. Frozen sections of the uterus, with fœtus *in situ*, were exhibited. A well-marked ridge projecting into the cavity of the uterus was the subject of considerable discussion, it being the opinion of Dr. Andrews and Dr. Maxwell that this represented the retraction ring. Post-maturity of the fœtus was discussed and the recorded cases were criticised. Sections of the placenta were also shown but did not throw any light on the etiology and pathology of the condition.—Dr. Champneys said that he had felt contraction rings round various parts of the uterus, in some cases round one of the uterine cornua. The experiments of Kleinwächter showed that spontaneous delivery occurred in some of the most unpromising cases of obstructed labour. In such a case as that under discussion, where the patient was already septic, the choice of treatment was one of great difficulty.—Dr. W. S. A. Griffith suggested that the probable cause of the difficulty in delivery was not in the uterus but in the macerated condition of the fœtus. He wished to emphasise the value of version as a means of delivery after craniotomy if the uterus was not in a state of tonic contraction.—Dr. Eden remarked that the term contraction ring was inaccurate; it should be called the retraction ring. He could not accept the view advanced by Dr. Andrews and Dr. Maxwell as to the formation of this ring that it was the result of moulding on a body groove. —Dr. Andrews and Dr. Maxwell replied.

MEDICAL SOCIETY OF LONDON.

Discussion on the Prognosis and Treatment of Acute Anterior Poliomyelitis.

A meeting of this society was held on March 23rd, Dr. J. Kingston Fowler, the President, being in the chair.

Dr. J. S. Risien Russell, in opening the discussion, referred to the importance of excluding cases of Landry's paralysis and those of acute toxic polyneuritis before a true estimate of the prognosis in poliomyelitis could be obtained, for the former of these diseases was infinitely more fatal than poliomyelitis, while recovery from the latter was much more perfect than usually obtained in this affection. Even allowing for the possibility that some cases might die in the acute stage of the illness without being recognised poliomyelitis was by no means a fatal disease. It was, however, not safe to venture an opinion until there was evidence that there had been no extension of the paralysis for at least from 24 to 48 hours. Some return of power in the paralysed parts was to be expected even in the most severe cases that lived, but in a large proportion the amount of residual defect was most disappointing, although there were notable exceptions to this rule. The more rapidly power returned the better the chances of a good result. An electrical examination was of some value in forming an estimate as to which muscles were likely to recover most, as those which still responded to faradism after three weeks might be expected to make a good recovery. It did not, however, follow that a muscle which did not respond to the interrupted current after this period was not capable of some recovery, for in reality it was compatible with a considerable amount of improvement, although full recovery could never be expected. Attention was called to a class of case in which poliomyelitis was probably responsible for a uniform want of development of a limb in which, nevertheless, no one muscle was paralysed or specially atrophied and in which all of the movements could be performed. In this class of case, as in a case of acute poliomyelitis, a progressive muscular atrophy might be encountered later in life but this was a rare sequel. Beyond keeping the patient at rest in bed, with the skin and bowels freely acting, the less active treatment the better in the acute stage of the affection. Pain must, however, be relieved and if local applications failed morphine might be required. In the case of a child it was much more important to keep the patient quiet than to risk the disturbance caused by the attempt to counter-irritate the spine or to secure the prone position. Provided there was no fever and pain did not prevent it massage should be commenced in from ten days to a fortnight, and should be combined with passive movements to which resisted movements should be added in due course, while the patient was encouraged to practise the voluntary contraction of the muscles, no matter how slight a return of this there might be. In spite of statements that Dr. Russell had seen to the contrary treatment by a skilled masseuse was far superior to any rubbing that a child's mother or nurse could be taught to give. He was also compelled to differ from those who were of opinion that electricity was of no use in the treatment of the affection as galvanism was a most useful therapeutic agent. Drugs played an altogether unimportant part in the treatment of the disease beyond any general effect on the system that might be desired, although it was the rule to give strychnine in the hope that it might have a more direct influence on the course of the malady. While fully alive to the important advances that had been made in the surgical treatment of the affection he was of opinion that the other methods of treatment should be fully tried before recourse was had to surgery. He, however, warned physicians not to be too conservative but to avail themselves of the assistance of the surgeon at the proper time, for in a large proportion of cases there was much that he could do to supplement the medical treatment of the case. While strongly deprecating the use of heavy and cumbersome instruments to effect this he hoped that physicians would be careful to adopt such measures in treatment as were calculated to prevent deformities and not lay themselves open to the charge that they had allowed to occur what the surgeon would have prevented. He hoped to hear from surgeons who were to take part in the discussion the relative merits of the different surgical measures that were in vogue and how the best results were obtained. The field for tendon transplantation must be much wider than that for nerve grafting, which must be applicable to but a small proportion of cases. Some attempt should be made to arrive at a general agreement as to the time when these operations as well as that of arthrodesis with a view to obtain fixation should be performed.

Dr. C. E. Beevor thought in regard to prognosis that the electrical reactions were important; if a muscle reacted to faradisation three weeks to a month after the onset of the illness then the prognosis would be that the muscle would recover; as long as there was galvanic reaction there was the chance of recovery and even up to 12 months from the was passed from the bowel through one of these into an abscess cavity and thence into the bladder. (*The diverticular origin of this case was evidently not recognised by the author.*)

CASE 100 (Hepner (33), 1902).—Female, 64 years of age. Life-long constipation; thin; 14 months before, pain on micturition and defæcation coming on suddenly after lifting a heavy weight; abdominal pain and fever. Passed fæcal masses and a pear-pip in the urine. Diagnosis: fistula between the bladder and the bowel due to a previous attack of appendicitis.

Operation.—A communication between the bladder and the sigmoid flexure, 12 centimetres above the rectum was found. This was due to the presence of a diverticulum lined with mucous membrane, two and a half centimetres long and one centimetre wide. Recovery.

CASE 101 (referred to by Moynihan (51)).—Vesico-colic fistula of diverticular origin.

CASE 102 (Waldvogel (74), 1902).—Male, 35 years of age. Long history of difficult urination. Signs of fistula about a year before death.

Necropsy.—Marked stenosis of the sigmoid flexure from inflammatory thickening; above this is a row of deep diverticula. The thickened and stenosed area is adherent to the bladder; six openings—two lined by mucous membrane—lead from the gut into the tissue intervening between it and the bladder, and two of these enter the bladder directly. The gut also communicates with an abscess cavity containing fæculent material and a comparatively fresh apple-seed.

CASE 103 (Czerny, quoted Waldvogel).—Vesical fistula. Somewhat similar case.

CASE 104 (Herczel (34), 1899).—Male, 43 years of age. Irregular bowel action. Five months' symptoms of entero-vesical fistula with passage of air and fæces per urethram. Stricture of the bowel 12 centimetres from the anus; tumour felt in the left iliac fossa. Carcinoma of the sigmoid flexure diagnosed; at operation the bowel was found to be adherent to the bladder. Subsequent colotomy and death.

Necropsy.—Multiple diverticula containing fæcal matter in the whole of the rectum; one had given rise to fistula; stenosis of the bowel; small abscess cavity outside of it. The fistula was 25 centimetres above the anus.

CASE 105 (Heine (32), 1904).—Male, 73 years of age. Diverticulum of the sigmoid flexure adherent to the bladder. Also a vesico-colic fistula, *probably* of the same nature.

It will be observed that many of the foregoing cases are marked with an asterisk (*), denoting, it should be explained, that they are previously inedited cases.

Leeds.

A CASE OF DIAPHRAGMATIC HERNIA.

BY H. O. WILLIAMS, M.R.C.S. ENG.,
L.R.C.P. LOND.,
SENIOR HOUSE PHYSICIAN AT THE METROPOLITAN HOSPITAL.

THE following case was admitted to the Metropolitan Hospital on Nov. 9th, 1907, under the care of Dr. Edmund Cautley, for shortness of breath. The child, a girl, aged nine months, born at full time, apparently healthy, was breast-fed, and did well until a fortnight before admission when she had an attack of vomiting and became short of breath. During this fortnight vomiting continued and she lost flesh rapidly. There was nothing of importance in the family history. On admission the child was pale and thin; the flesh was flabby and the skin was inelastic. The eyes were dull and sunken. The temperature was 99° F., the pulse was 132, and the respirations were 60. The apex beat was best felt about one inch to the right of the sternum in the sixth intercostal space. The superficial area of cardiac dulness was obliterated. The heart sounds were natural. The right side of the chest was resonant all over, the resonance extending in front to the costal margin. Breath sounds were distinct all over this area. On the left side there was dulness to percussion over the left lower lobe behind, extending to the mid-axillary line. No breath sounds were heard over this area but an occasional râle was heard in the left axilla. The signs over the upper lobe were natural. The abdomen was large and distended and the edge of the liver could be felt below the umbilicus. The spleen was not palpable. On the 11th the note was still dull over the left lower lobe behind reaching to the mid-axillary line. Distant breath sounds were heard over this area and a patch of friction at the base and at the apex of the lower lobe. There had been no vomiting since admission. On the 15th the child vomited four times and had five loose undigested stools. There was a much better note over the left lower lobe, but the breath sounds were still absent. On the 19th vomiting continued. The patient would not take food and had to be nasally fed. She had lost five ounces in weight since admission. The note was quite dull over the lower lobe and no breath sounds could be heard. The chest was explored in two places with negative results. On the 25th the general condition of the child seemed much better. She had gained five ounces in the last six days. The respirations were now 32, but the temperature was a little raised. The vomiting stopped. The note over the left lower lobe was now quite resonant but no breath sounds could be heard. On the 28th the note over the left lower lobe was resonant. The breath sounds were distinctly heard over this area. No râles were heard. The patient vomited once during the last seven days. On Dec. 2nd she was gaining weight. There was no more vomiting. The note was resonant over the left lower lobe. No breath sounds were heard. On the 5th there was some consolidation of the right lower lobe. The temperature was 104°. On the 9th there was recurrence of vomiting and the patient was losing weight. On the 10th respiration was shallow and rapid. The child was cyanosed. There was a good note over the left lower lobe. No breath sounds could be heard. The abdomen was distended. On the 11th there were considerable cyanosis and dyspnœa. The left lower lobe was resonant. The child died from failure of respiration.

Necropsy.—The body was that of a small child, sparsely

Dr. **DUDLEY W. BUXTON** said no doubt it would be adopted by all careful anæsthetists, but he thought it was questionable how far it was safer than a general anæsthetic. Most of the cases which he had seen had no shock or vomiting, but he had seen extreme shock, extreme faintness, and extreme respiratory shock. The personal factor must be taken into account. Some people were very frightened of a general anæsthetic, others were more affected by being conscious during an operation. He was of opinion that the after-effects of general anæsthetics had been exaggerated. But he thought that they *must* make up their minds that a new method of great value when properly mastered and applied to suitable cases had come amongst them, and he would be very glad to add it to his armamentarium.

Mr. **V. WARREN LOW** had used Mr. Barker's solution heavier than cerebro-spinal fluid. He had had one or two failures. A patient of his much preferred spinal anæsthesia while a friend who had had an operation under a spinal anæsthetic would have a general anæsthetic another time as he suffered from general muscular pains. He thought that vomiting was less frequent than after general anæsthesia.

Mr. **F. R. HUMPHREYS** asked Mr. Dean whether he had had any complications, because in foreign literature he had found mention of eight cases of diplopia, two cases of death (only one could be fairly attributed to stovaine), six cases of respiratory paralysis, and a large number of cases of vomiting, headache, and pain in the back. In Vienna they seemed to think that tropacocaine was the drug of the future.

Dr. **G. H. COLT** said that the chief difficulty was to find the way into the spinal canal. They must find the right angle and go straight in. In general practice a man could do much single-handed with this method.

Mrs. **F. M. DICKINSON BERRY** was surprised that so many of Mr. Dean's cases were of advanced age, as German authorities said it was contra-indicated in very old or young subjects.

Dr. **J. BLUMFELD**, speaking as one who intended to learn the method, inquired whether sitting up or lying on the side was the best position of the patient when the puncture was made.

Mr. **DEAN**, in reply, said that he had not used the method in Trendelenburg's position, but Kroenig said that an angle of 30 degrees was safe. He had had no cases of vomiting. He believed that no failures would occur if a second dose (half the first) were given when one dose did not succeed. He had seen anæsthesia extend as high as the clavicle without respiratory paralysis. He preferred to have the patient sitting up when he made the puncture. He saw no reason to withhold it from old or young.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

The Relation of Entozoa to the Mucous Lining of the Alimentary Canal.—The Rôle of Filaria in the Production of Disease.

A MEETING of this society was held on March 20th, Sir **PATRICK MANSON**, the President, being in the chair.

Mr. **A. E. SHIPLEY** (Cambridge) read a paper on the Relation of Entozoa to the Mucous Lining of the Alimentary Canal. In his communication, which was illustrated by a large number of excellent epidiascope slides, Mr. Shipley traced the various entozoal infections of the lower animals and man and demonstrated the injuries and septic consequences which might result from the presence of parasites in the alimentary canal. After describing various intestinal parasites of the grouse, the common fowl, and the horse, he reviewed the state of our knowledge as to the influence of entozoa in originating disease in man and suggested that appendicitis might be caused by trichocephalus trichiurus.—Dr **O. W. DANIELS** stated that he did not agree as to the connexion of trichocephalus and appendicitis; he thought he was supported in this by the fact that though natives of the tropics were deeply infested by that parasite appendicitis was very rare.—Sir **R. HAVELOCK CHARLES** said that his experience was that appendicitis was not uncommon in natives of Lower Bengal.—After remarks by Dr. **L. W. SAMBON** and Dr. **R. T. LEIPER**, both of whom agreed that trichocephalus had no influence in originating appendicitis, the **PRESIDENT** said that it was generally believed by medical men, and statistics fully supported the belief, that trichocephalus and appendicitis had no definite connexion.

Dr. **W. T. PROUT** read a paper on the Rôle of Filaria in the Production of Disease. He said that the adult filaria loa was a worm the habitat of which appeared to be the connective tissue and which became visible when it approached the surface in any situation where the tissues were thin and lax, as, for example, in the scrotum. Evidence was accumulating that a micro-filaria showing a certain amount of diurnal periodicity was the embryonic form of that worm and he described a recent case which illustrated that point and two other cases where the presence of the worm was associated with certain cutaneous phenomena. He thought that there were a sufficient number of recorded cases to justify him in associating the presence of filaria loa with Calabar swellings, but he attributed the local phenomena to the mechanical irritation of the adult worm as it forced its way through the connective tissue near the surface. The œdema which resulted was intensified by the rubbing and scratching which took place as a consequence of the itching, and the intensity of the phenomena depended to a large extent upon the sensitiveness of the individual's skin. Filaria nocturna was associated with a long list of diseases, which included lymphangitis, abscess, varicose glands, lymphatic varix, lymph scrotum, elephantiasis, &c., in other words with a series of diseases connected with inflammation or obstruction of some part or other of the lymphatic system. For the sake of argument, he assumed that elephantiasis was not due to filaria nocturna and criticised the various suggestions that had been put forward to see whether there was not another explanation which would account for the production of that and other so-called filarial diseases. The invariable association of filaria nocturna with elephantiasis had not been clearly proved. The production of the disease experimentally and the recognition of the parasite afterwards had still to be shown. Radcliffe Crocker, in discussing the pathology of elephantiasis, both sporadic and endemic, had said: "The disease is consequent upon an occlusion of the lymphatic channels of the part affected, independent of the cause and nature of the obstruction, and whether it is at the trunk or periphery of the lymphatic circulation." Dr. Prout described a case where obstruction in a main trunk caused extensive elephantiasis, and no doubt similar cases might occasionally be found in the tropics. But he was inclined to believe that the vast majority of cases of elephantiasis in the tropics was of peripheral origin due to a lymphangitis arising peripherally, caused by the introduction of a specific micro-organism, and resulting in the gradual narrowing and obstruction of the peripheral lymph vessels. Radcliffe Crocker had pointed out that in a temperate climate erysipelas, either as a severe or diffuse cellulitis or from repeated attacks, was one of the most common causes of lymphatic obstruction. He ventured to suggest that during the attacks of elephantoid fever an attempt should be made to examine the serum, and he looked forward to the time when some skilled observer would demonstrate the presence of some specific organism.—The **PRESIDENT** said that discussion on Dr. Prout's very valuable paper, with the reading of his other communications, would be deferred till the next meeting.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Scientific versus Surgical Bacteriology.—Exhibition of Cases and Specimens.

A MEETING of this society was held on March 20th, Dr. **J. ALLAN**, the President, being in the chair.

Dr. **A. S. F. GRÜNBAUM** read a paper entitled "Scientific *versus* Surgical Bacteriology," to show the baselessness for the custom in some hospitals of excluding dressers from the educational advantages of the post-mortem room or dissecting room students and others from surgical wards. He invited concurrence with the following propositions: there was no evidence to show that the atmosphere or surroundings of the dissecting-room or post-mortem room were bacteriologically more dangerous than of the operating theatre or surgical wards; there was no evidence to show that the hands of students working in these rooms were bacteriologically more dangerous or difficult to disinfect than of those who were not so working; there was this same fact I attribute the success of the treatment employed.

The form of treatment in which I am particularly interested—viz., electricity—has been frequently tried in this disease but with disappointing results. When I came to look into this matter I found that in every case the method employed was the faradic current applied by means of a wire brush. Bearing in mind that pain is a usual if not the chief symptom it is strange that a method should be used which from its very nature was practically bound to make the condition worse. Indeed, if any benefit took place after such applications, I should say it could only be in spite of, rather than on account of, such treatment.

Except in those very rare cases of neuralgia where the counter irritant action of an induction coil is useful, pain is a direct contra-indication for the use of induction coil or rapidly varying currents of any kind. Is it any wonder then that electrical treatment has so far been unsatisfactory in the treatment of this condition? It would never occur to me to use any but the constant current, in the first instance at least, but it was only in the last case that it was given a fair trial. In the first the patient was so overjoyed to find he had not anæsthetic leprosy that he took the first available ship to India without waiting to undergo a thorough course of treatment. In the second the patient was so disappointed at not being completely relieved after some half-dozen applications that treatment was given up. The case was one of considerable standing, and patience and persistence were necessary to get good results. In the third case treatment was begun early. The indifferent electrode—negative—was placed across the lumbo-sacral region, while the active electrode was applied over the affected area, and especially over the place where the nerve pierces the fascia. This electrode was one of 100 square centimetres area and was moved to a fresh part of the affected area every two or three minutes. The current passing varied between 30 and 50 milliampères. Definite improvement began after the third application and steadily progressed. Eight applications were given in all, the last being on Dec. 10th, 1907. The patient has remained perfectly well ever since but in view of his hunting proclivities recurrence is not improbable.

Queen Anne-street, W.

PERFORATION OF THE ŒSOPHAGUS BY A RABBIT BONE:

SEPTIC INFLAMMATION OF THE MEDIASTINUM; ULCERATION INTO THE AORTA; DEATH FROM HÆMORRHAGE.

BY R. LAWFORD KNAGGS, M.C. CANTAB.,
SURGEON TO THE LEEDS GENERAL INFIRMARY.

A YOUTH, aged 16 years, was eating some rabbit-pie when something "stuck in his throat." After his meal he went to see a football match and on his return he vomited. From that time he had had a painful sensation in the lower part of the sternum and had taken practically no solid food, but this was apparently because he had no appetite for it and not from any difficulty in swallowing. Two days after the occurrence he went to the Leeds General Infirmary and the resident casualty officer passed a probang into the stomach without meeting any obstruction. In the interval before his admission on the seventh day, the patient stated that he had been under the care of a medical man who said that he was suffering from pneumonia. On the day of admission he began to vomit large quantities of bright blood and he passed dark blood from the rectum two or three times.

When admitted to the infirmary the lad was extremely ill, very pale, sweating profusely, and mentally quite clear. He was not in pain. He brought up a small amount of bright frothy blood. The pulse was 130 and poor, the respirations were 30, and the temperature was 98° F. There was a definite pericardial rub and signs of fluid at the base of the left chest, which on exploration proved to be thin turbid odourless serum. Death occurred four hours after admission.

Post-mortem examination by Dr. G. W. WATSON.—On opening the body there was marked œdema of the tissues over the front of the chest. When the sternum was removed an acute inflammation of the tissues in the mediastinum was found. The soft tissues of the whole mediastinum extending quite down to the diaphragm, but chiefly affecting the upper part, were of a dirty greyish-black colour and there was also a little exudation. There was no offensive odour. The pericardium was adherent to the pleura on the left side and when the sac was opened *in situ* an extensive simple plastic pericarditis was revealed. There was slight recent pleurisy in the left chest and about half a pint of turbid effusion. In the œsophagus, about three inches below the cricoid cartilage, were two perforations situated opposite to one another, as if caused by something that had lain transversely and been impacted in the tube. There was very little sign of inflammatory reaction of the tissues in these situations. The perforation on the left side extended into the cellular tissue for about an inch. On the right side a probe could be passed through the other opening in the œsophagus into the middle of the dirty-looking material in the mediastinum. Further investigation showed that the abscess in the mediastinum had ulcerated into the aorta just at the commencement of the descending portion of the arch on its upper and posterior aspect. The ulcerated aperture was three-quarters of an inch distant from the origin of the left subclavian artery. A probe could be passed without any force whatever from the œsophagus into the aorta. No bone could be found anywhere. All the abdominal viscera were quite healthy, but the stomach and intestines were full of pure blood. The blood in the stomach formed a large clot which was a complete cast of that viscus and from it there was a prolongation into the œsophagus for several inches. At the other end the pyloric portion was continued into a cast of the first and second parts of the duodenum.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Phagocytosis carried out by means of Melanin.—Administration of Tuberculin (T.R.) and other Vaccines by the Mouth, together with (a) Normal Saline Solution; and (b) Fresh Horse Serum.

A MEETING of this section was held on March 24th, Dr. S. J. GEE, the President, being in the chair.

Mr. S. G. SHATTOCK and Mr. L. S. DUDGEON communicated some observations upon Phagocytosis carried out by means of Melanin, more particularly with reference to the part taken by the leucocytes in infective diseases.[1] When melanin (from the eye of the ox) in salt solution was mixed with immune blood the phagocytosis might be below normal, or normal, or considerably higher. Melanin was opsonised. An immune serum could be largely deopsonised by saturation with melanin. That could only result from opsonisation of the melanin. Conversely, saturation of a tuberculous serum with tubercle bacilli largely reduced the phagocytosis of melanin. That showed that the chief increase of opsonin was not of a specific kind. The phagocytosis of melanin, however, was diminished after heating the immune serum. In this Mr. Shattock's and Mr. Dudgeon's observations accorded with those of R. Muir and L. B. M. Martin, which proved that thermolabile opsonin (in normal blood) was non-specific, since it could be removed by very different micro-organisms. Mr. Shattock and Mr. Dudgeon maintained that the leucocytes of immune blood were in some cases more active than those of normal blood. An increased phagocytosis of melanin occurred in some cases if melanin was presented to the "washed" leucocytes of an immune blood in normal serum, as compared with washed normal leucocytes in normal serum; or, if melanin was presented to "washed" immune leucocytes in immune serum, and to "washed" normal cells in immune serum, the ingestion done by the patient's cells was in many cases greater than that done by normal cells. They concluded, therefore, that the calculation of the opsonic value of the patient's serum alone did not give a complete estimate of the patient's hæmophagocytic resistance; it might be too high or too low, or as a coincidence it might exactly represent it. The method of making a hæmophagocytic estimate though, as a rule, none were found on them in health. Dead rats had been picked up near the cages and their fleas, having no hosts, took refuge in the hair of the guinea-pigs. After this discovery guinea-pigs were employed to trap rat fleas in plague-infected places. The stomachs of these fleas were found to contain many actively living plague organisms. Captain Liston found by actual observation that pulex cheopis would attack man when its natural host was absent. The fleas collected from individuals suffering from plague were in many cases those peculiar to the rat. Lieutenant-Colonel Bannerman and Captain Liston built a set of experimental go-downs or cabins in which to carry on a series of experiments as nearly approaching those found in the native town as possible. As regards the conveyance of plague infection through food soiled with the excreta of rats Lieutenant Colonel Bannerman narrated the experiments carried out by the Plague Commission. Of 6000 rats naturally infected with plague the primary bubo was situated on the neck in 74 per cent. and in the inguinal region in 25 per cent.; in no single case were mesenteric buboes present. On the contrary, in the case of 155 rats infected by feeding the mesenteric glands were affected in 70 per cent., the neck glands in 35 per cent., and the inguinal glands in a single case. Numerous experiments were made by feeding rats with the urine of patients dead from plague and in no case did the disease develop in them. Many rats were inoculated with the fæces of rats dead from the plague and only 2·9 per cent. died from the disease. Guinea-pigs also fed on infected food and kept under most insanitary surroundings never developed plague. It might confidently be stated that in India at least food contaminated with plague material had nothing whatever to do with the spread of the disease. On the contrary, Simpson was able to infect all the domestic animals of China (with the exception of the dog) by feeding them on huge quantities of plague-infected viscera and it would appear as if there were some curious difference in plague in India and in China. It had been a favourite theory that plague was spread through contamination of the soil. The natives went barefoot and often ate their food from leaves placed on the floor and therefore liable to contamination. Many investigators had, however, constantly failed to find the presence of bacilli in the soil and experiments made recently showed that plague bacilli rapidly perished in the presence of saprophytic organisms in the soil and disappeared after four days. After detailing the experiments carried out by the Commission, which showed that only a very small proportion of animals exposed to infection contracted the disease and then only when the floors had actual pools of infected liquid on them, Lieutenant-Colonel Bannerman showed that animals might contract plague when carefully protected from contact with the soil and that just as many guinea-pigs contracted plague in disinfected rooms in Bombay as in rooms not so treated. The latter infection was due to the presence of rat fleas which were not affected by the (1 in 750) solution of perchloride of mercury. Lieutenant-Colonel Bannerman then dwelt on the distinguishing features of the rat flea and narrated experiments to prove that fleas from infected rats conveyed the disease to healthy animals. In 11 out of 16 such experiments (= 69 per cent.) the healthy white rat from England contracted the disease in this way, while with Bombay rats the percentage was 38 per cent. The smaller percentage was probably due to a certain number of the latter rats being immune to the disease. Many hundreds of successful flea-transmission experiments were also carried out with guinea-pigs. To prove that mere proximity to diseased animals was incapable of transmitting the disease 50 healthy flea-free guinea-pigs were placed in a flea-proof go-down along with ten guinea-pigs inoculated with a virulent culture of plague bacilli and fed with contaminated food; nine of the infected animals died and yet none of the healthy guinea-pigs contracted plague. In a flea-proof go-down 49 guinea-pigs had been living in health for three weeks when 221 fleas taken from the bodies of guinea-pigs dead from plague were introduced, and after six weeks' interval the whole of the guinea-pigs had succumbed to plague. A flea could jump barely six inches, so in a flea-infested go-down the guinea-pigs were divided into three groups of four each, one allowed to run on the floor, one confined in cages two inches above the floor, and the third group in cages two feet from the floor. Two days afterwards 125 fleas were taken from those on the floor, 27 from those in the low cages, and none from those in the high cages. All the animals in the first two groups died but none in the third group. The same results were obtained when monkeys were employed. The season in which epizootics were readily produced experimentally and spread rapidly corresponded with that of the plague epidemic. Experiments were made to prove that plague-infected houses were dangerous because of the fleas which they contained. The first fact discovered was that nearly all the fleas caught on guinea-pigs which had been allowed to run about these infected houses were rat fleas and were present in large numbers. The second fact was that a large number of such guinea-pigs died from plague; of 189 houses experimented on in Bombay and in the Punjab 40, or 21 per cent., proved infective to guinea-pigs. Even after disinfection of plague houses by thorough washing with perchloride of mercury solution (1 in 750) and disinfection with the fumes of sulphur which were sufficient to destroy the plague bacilli, it was found that guinea-pigs became infected in nine out of 31 such houses, or in a proportion of 29 per cent. This was exactly the same percentage that proved infective out of 42 other rooms experimented with in the same season and which had not been disinfected in any way. The average number of fleas caught in these disinfected rooms was 40 and in one instance as many as 263 were present; the average in 13 rooms not disinfected was 34. The great majority of fleas caught on the guinea-pigs placed in the plague-infected houses were rat fleas. In another series of experiments in plague-infected rooms it was shown that animals contracted the disease although protected from floor infection and from all contact with plague-infected rats, provided that they were not likewise protected from fleas. For this purpose pairs of animals were placed in the rooms in cages so contrived that one was flea-proof, while the other was open to the entry of these insects. In 63 experiments all the protected animals remained healthy, while eight, or 13 per cent., of the unprotected ones developed plague. A variation of this experiment was made by protecting the animal in the cage, not by gauze but by sticky fly-paper, on which the fleas were caught in trying to reach their victim. In 59 such experiments all the animals so protected remained healthy, while 9 per cent. of those not so protected developed plague. In the case of these caged animals the average number of fleas per guinea-pig was 3, as contrasted with 20 to 40 in those allowed to run over the rooms freely. Of 401 fleas caught on the fly-paper, 221 (= 55 per cent.) were rat fleas; 148, or 37 per cent., were human fleas; and 32, or 8 per cent., were cat fleas. A greater number of rat fleas were found in plague-infected houses than in healthy dwellings. The logical conclusion would appear to be that rooms were dangerous because of the infected rat fleas in them and that the soil and air had no infective properties. It remained to prove that the rat flea was the cause of the transmission of plague from rat to man. It had to be remembered that the germs of plague gained access to the body through the skin; pneumonic plague might be ignored, as it occurred in only about 2·5 per cent. of all cases. As regards the site of the buboes, in practically every case the primary bubo developed in the group of glands which stood in direct lymphatic connexion with the area of skin which had been inoculated. All evidence went to negative the idea that plague was ever naturally conveyed through the digestive tract but that it indicated the skin as the real point of entry. A definite time relationship was seen between the Rattus epizootic and the epidemic—the mean interval varied from 10 to 14 days. Captain Liston showed that rat fleas attacked man and other animals in the absence of their natural hosts. When a man placed his hand into a cage containing rat fleas they jumped on to the skin and in time would bite; unless very numerous, however, they would not do so in the presence of rats. When starved for 72 to 96 hours they readily fed on man. The members of the Plague Commission always wore top boots on visiting plague houses and the bare-legged attendants were only saved from infection by regular injections of Haffkine's anti-plague vaccine. The stomach of a flea was large enough to contain many plague bacilli and these germs multiplied in its stomach. The bacilli were passed in abundance per anum while the insect was sucking blood on the skin. Such fæces were infective through the pricker wound even without rubbing. The duration of infectivity of fleas had been estimated as 15 days during the epidemic season and seven days in the off season. A flea might survive for three weeks and thus there was ample time for it to be transported in clothing from place to place with passengers and testis throughout its functional activity. The nature of his experiments was briefly as follows. He injected two hens with a fresh preparation of cock's testes beginning on Feb. 1st, 1907. The injections were continued every day until Oct. 4th with the following results. The combs and wattles of the hens grew to a very large size and the hens stopped laying eggs about the middle of March. This growth of the combs and wattles seemed to reach its maximum at about the end of June. From March to October these hens seemed always to wish to attack any cock which was placed in the greenhouse where they were kept. On Oct. 4th the injections were discontinued and on Nov. 9th the combs and wattles had shrunk back to the normal size found in the hens before the experiment was commenced. The size of the combs at the maximum was about eight times that found in the same hens before the experiment and after Nov. 9th. In two cases Shattock and Seligmann had recorded a shrinkage of the comb after castration of the adult cock.

---

[1] This communication is based upon one made to the Royal Society of London through Professor J. Rose Bradford.

Dr. W. S. **Lazarus-Barlow** read a paper on the Relations of Endothelioma to other Forms of New Growth. He brought forward the view that certain varieties of growth met with chiefly in the breast and the cervix, and generally described respectively as spheroidal cell and squamous-cell carcinoma, were identical in appearance and differed from typical carcinomata of those types by the presence of lumina, by the characters of the cells and their nuclei, and by the general arrangement of the cell masses. He then pointed out that these characters, together with a great tendency to variation in appearance in metastases, were best to be explained on the view that they had originated from endothelium. He advocated the same view for uterine growths that appeared to consist of both carcinoma and sarcoma and for a large number of those mouse tumours which showed a great deviation from the original tumour after repeated transplantation. Upon this view about 10 per cent. of uterine and mammary carcinomata were endotheliomata.—Dr. E. F. **Bashford** pointed out how the investigation of mouse cancer was of the greatest importance because of its freedom from the limitations necessarily attaching to the clinical and pathological study of cancer. He referred to Gierke's work showing that mouse tumours were epithelial and not endothelial and explaining how the peculiarities of mouse tumours ceased to be of importance when the differences between the histology of the mouse and of man were understood. In considering spontaneous tumours of the mouse as opposed to inoculated tumours it must be remembered that the anatomical conditions were distinct. In the case of spontaneous tumours infiltration of the thoracic walls and of the muscles and of the skin was common. In the case of the transplanted tumours he acknowledged that infiltration occurred in a small proportion of cases, but when a mass of tumour pulp was introduced under the skin of the mouse there was established a different condition of things from that found in the development of a new growth. Therefore in experimental work conditions were not induced exactly corresponding to those seen in spontaneous tumours.—Dr. L. **Courtauld** also spoke.

Mr. C. W. **Rowntree** read a communication dealing with the Presence of Prickle Cells in Tumours originating, or supposed to originate, in squamous epithelium. He pointed out that as prickles were of such constant occurrence in this situation it might be supposed that new growths which originated there would contain them. He stated that this was generally the case both in the primary growth and its metastases, but that there was a class of tumour originating in situations such as the tongue and cervix uteri which departed from the common type in that they did not possess prickles and also had other points of similarity which suggested the possibility of their constituting a separate class of new growth.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Myomectomy during Pregnancy.—Difficult Labour.

A MEETING of this section was held on March 12th, Dr. **Herbert R. Spencer**, the President, being in the chair.

Dr. **Walter C. Swayne** read a short communication on Myomectomy during Pregnancy and described two cases operated on by him. Case 1: A primipara, aged 40 years, pregnant five months, had a solid, rapidly increasing, painful tumour growing from the fundus uteri. After laparotomy a pedunculated fibroid of the size of an adult head was removed from the fundus. The flattened pedicle was transfixed and the peritoneum was sewn over it. A smaller fibroid, which was sessile and situated behind and below the first, was also enucleated. Recovery was uninterrupted. Pregnancy had not been interrupted two months later, after which the patient was lost sight of. Case 2: Multipara, aged 35 years, pregnant four and a half months, with abdominal pain and a bilobed tumour rising out of the pelvis, the left lobe being hard and the right soft and elastic. Laparotomy showed a fibroid growing from the right cornu of the pregnant uterus which had undergone axial rotation, so that the fibroid lay on the left. The rotation was untwisted with some difficulty and the fibroid was then enucleated. Pregnancy was interrupted a month after the patient left the hospital. Dr. Swayne pointed out that fibroids of the pregnant uterus required operation if causing pain, pressure symptoms, axial rotation of the uterus, or symptoms of twisted pedicle. Rapid increase with pain might point to degeneration. Pregnancy was not necessarily interrupted. Accurate apposition of the gap in the uterine wall was of great importance

Dr. J. H. **Dauber** communicated a case of Pregnancy complicated by a large and fixed Retroperitoneal Fibromyoma which completely blocked the pelvis besides filling the abdomen. The patient was a young married woman three months pregnant She had become alarmed at her rapidly increasing abdominal girth. Operation took place on Dec. 20th. All the resources of surgery were needed to control the hæmorrhage after enucleation of the tumour. Chiefly on this account it was found impossible to preserve the uterus. The case was an example of a fibroid of such dimensions and so situated that neither delivery *per vias naturales* nor progression to full term was possible and early operation was the only safe line of procedure. In this instance recovery was rapid and complete.—In the discussion on these communications the **President** said that, while not criticising the three cases reported, in which the operations were done for definite and serious indications, he felt bound to express his strong opinion that operations in the case of fibroids complicating pregnancy were rarely called for and that myomectomy, which was occasionally urgently demanded in the case of very large, or impacted, or rotated tumours, was in relation to the frequent occurrence of this complication of pregnancy very rarely required and, as the cases exhibited that night showed, was attended by considerable risk. When practicable, the operation should be postponed till the child was viable.—Dr. F. H. **Champneys** entirely endorsed the remarks made by the President. He had himself had a long experience of pregnancies complicated by fibroids. It was true that in exceptional cases he had been compelled to adopt serious measures, such as Cæsarean section, but he had frequently been consulted in cases in which the presence of a fibroid had caused alarm to the medical practitioner, but, without any interference, the patients had borne, not one child, but a series, with perfect ease and safety. In his experience the cases requiring serious interference were extremely rare.—Dr. G. E. **Herman** agreed with the last speaker that the mortality of myomectomy in pregnancy, as quoted in the statistics mentioned by Dr. Swayne, was much too high. He narrated a case where he had enucleated a fibroid from a pregnant uterus and the woman was delivered six months later of a full-term child.—Dr. **Amand Routh** agreed with Dr. Swayne's statement that fibroids complicating pregnancy should not be interfered with unless producing urgent symptoms. Unfortunately, Dr. Swayne had quoted statistics, somewhat obsolete in date, tending to show that fibroids were so serious a complication of pregnancy that operations were frequently justifiable. Dr. Routh thought these statistics quite untrustworthy. He had collected statistics[1] showing that the maternal mortality of such cases under modern methods was only slightly in excess of the normal and that the danger to life was not so much due to risks during labour but to sepsis afterwards, for if the endometrium became infected a submucous or an intramural fibroid almost always became infected also. He showed that abortion did not more often occur where fibroids were present, though labour often ensued a few weeks before full time, and urged strongly that no operation should be performed till fœtal viability, unless absolutely essential, so as to save the two lives involved. He had only twice had to perform Cæsarean hysterectomy at or near full term and never at an earlier date, though he had seen many cases of fibroids blocking the pelvis in the early months. The fibroids in such cases almost increased power of dealing with the confirmed inebriate. —After some remarks by the President, Mr. Mark Robinson gave details of experimental work tending to show the destructive influence of small doses of alcohol on protoplasm and referred to the records of insurance companies as showing the vital as well as the economic value of abstinence. —Dr. M. G. Biggs spoke of the natural craving for stimulant and sedative as ineradicable and divided alcoholics etiologically into the two classes of "luxury" and "misery" drinkers. In his opinion it was impossible to prove that moderate doses did harm.—Dr. L. S. McManus gave instances to show that heredity was not a necessary factor, while Dr. S. R. Dyer held that among the criminal classes heredity was a distinct factor.—Dr. W. G. Dickinson said that in his experience a certain proportion of women alcoholics were curable.—Dr. D. M. Aitken found that among women alcoholics gynæcological cases were the most difficult to deal with.—Dr. V. Ryan gave an interesting description of his experience of the geographical distribution of alcoholism, instancing extraordinary methods of obtaining alcoholic stimulation which he had seen in Manchuria and South Africa.

---

[1] Brit. Med. Jour., Oct. 3rd, 1903.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 6th, Mr. Richard Lake, the President, being in the chair.—Dr. Andrew Wylie read a paper on Foul Breath, its Causes, Pathology, and Treatment. He said that fœtor of the breath was purely subjective, entirely objective, or both. There were several different kinds of fœtor, such as the putrefactive, the sulphuretted hydrogen, the garlic, the sweetish, and the toxic types. Fœtor was classified according to the different regions responsible for its source, as diseases of the nose and accessory sinuses, nasal obstruction and growths, and naso-pharyngeal diseases, imperfect deglutination and carelessness in oral and dental hygiene, affections of the tongue and gums, caries of the teeth and imperfect dentures, diseases of the follicles of the tonsils, tuberculous, syphilitic, and malignant diseases of any part of the nose, pharynx, and larynx, if cartilage or bone was involved; suppuration of the middle ear, bronchiectasis and abscess of the lung, foreign bodies in any part of the upper air passages, gastro-intestinal diseases, and in paralytic patients. Fœtid breath was found more or less in spirit and beer drinkers, in smokers, in those who take certain drugs, and in those who follow certain occupations. Bacteria were the cause of the trouble and the treatment was to find the cause and to remove it, or at least to reduce the activity of the bacteria.—Mr. W. H. Bowen read a paper on Pneumococcal Otitis Media. He stated his opinion that the pneumococcus was the organism usually causing otitis media at any age. The occurrence of otitis during epidemic diseases was not considered. Special attention was called to the onset of otitis media after operation on the nose and naso-pharynx and the etiology was carefully considered. The sponging over the face with cold water was strongly condemned and the importance of avoiding draughts and keeping the patient warm was emphasised. The otorrhœa of babies up to 18 months was considered and the comforter was looked upon as the strong etiological factor, so much so that Mr. Bowen labelled it "comforter otitis media." It was pneumococcal and should be treated by cleansing the mouth in addition to local treatment to the ear. The paper finished with a consideration of the signs and symptoms of acute infection of the mastoid antrum and cells, which was practically always due to the pneumococcus.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 13th, Dr. J. Walker Downie, the President, being in the chair.—Dr. C. O. Hawthorne gave an address on the Cerebral and Ocular Complications of Anæmia and the Probable Relationship of these to Thrombosis. He referred to the occasional cases of chlorosis, in which such symptoms as stupor, coma, convulsions, various paralyses, and double optic neuritis appeared more or less suddenly, and he related some case records where evidences of cerebral disturbance were limited to double optic neuritis and ocular paralysis. As in a certain number of the more severe cases necropsy had proved the intracranial lesion to be thrombosis of the cerebral veins and sinuses, it was at least probable that the same con- [illegible] on w [illegible] of optic neuritis and ocular paralyses [illegible] as the sole unusual events in con- [illegible]. The position was made still [illegible] hat between the two groups above defined there were cases showing intermediate degrees of cerebral disturbance. Hence a graded series of cases might be traced from those leading to a fatal issue down to such relatively slight events as optic neuritis and ocular paralysis. From this position it seemed safe to claim that the optic neuritis which, without other complications, was at times found in chlorotic women (and the same might be said of an ocular paralysis) was probably dependent on thrombosis in the intracranial veins or sinuses. Further support for such a suggestion might be found in the occasional occurrence of optic neuritis in acute anæmia and in suppurative diseases of the middle ear, in both of which conditions sinus thrombosis was a distinct possibility. Another complication sometimes seen in chlorosis was contraction of the visual fields which might assume characters that demanded the diagnosis of an intracranial lesion and this might quite well be a thrombosis. Other examples of the range of thrombosis in anæmia might be seen in the occasional occurrence of retinal embolism and in some cases of retro-bulbar neuritis.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on March 20th, Dr. W. Langdon Brown, the President, being in the chair.—Dr. Harold Pritchard read a paper on Specific Inoculations. He defined a vaccine as a standardised emulsion of dead microbes in saline solution and indicated the lines of treatment for obtaining beneficial results. Treatment was concerned with the process of increasing protecting substances in the blood. He discussed natural and artificial immunisation with special reference to the administration of small doses of specific vaccines when inoculation was used. He alluded to Sir Almroth Wright's views on sera and their manner of production and discussed the opsonic theory. He emphasised the importance of using vaccines obtained from cultures of the specific organism infecting the patient and indicated the methods of preparing the vaccine. Vaccines were most useful in chronic cases such as acne, old boils, carbuncles, &c., but were not of much use in acute cases.—Mr. H. W. Armit, of the Lister Institute, who took part in the discussion, said that Wright's opsonic index method was particularly unsatisfactory and that opsonins were not specific substances. He considered that the important substances were the antibodies of Ehrlich. Possibly the best description of antibodies as produced by foreign protein material is that by Nichol. In treating chronic cases with vaccines it was best to start with a very low dose and to go on up to a very high dose.—Mr. W. Girling Ball said that during a course of vaccine treatment the value of the opsonic index could be disregarded. He related his experience of treating chronic cases of staphylococcic infection, chiefly boils and acne. He also alluded to the importance for each patient to have a vaccine prepared from his own organism. He originally injected 500,000,000 organisms once a fortnight but he now used 60,000,000 every four or five days.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on March 11th, Dr. J. J. Cox being in the chair.—The meeting was devoted to a discussion on Rheumatoid Arthritis. In opening the discussion Dr. Cox pointed out that rheumatoid arthritis prevailed in this country to a considerable extent. Since 1883 up to the end of 1907 close upon 13,600 cases of the disease had been admitted to the Devonshire Hospital, Buxton, a yearly average of 566. Rheumatoid arthritis was held to be a specific morbid entity, due most probably to the action of some as yet unknown micro-organism, an auto-intoxication affecting individuals from very early years, much more common in females than in males, running an acute, subacute, or more insidiously chronic course, leading to progressive and often symmetrical degeneration of the joints and periarticular tissues, accompanied by general debility and associated with evidences of disturbance of the nervous system. The tendency of the disease was to become progressively worse, leading to much crippling and incurable deformity of the involved joints. It might begin as an independent affection or might be grafted upon other arthropathies, such as rheumatic, influenzal, or other bacterial conditions. Any profound disturbance of the general health might lead to its development. The treatment was unsatisfactory because the true causation was unknown. Dr. Cox suggested the establishment at the Devonshire Hospital of a research scholarship, the holder of which might by close study of the pathology, especially of the bacteriology of the disease, discover some means of proper and satisfactory treatment. This would be of national importance. The following took part illness there was always hope. It was only when the muscle did not react to either galvanic or faradic stimulation that the case could be regarded as hopeless.

Mr. A. H. TUBBY said that the intelligent anticipation of possible deformities from the disease was a most important part of the duty of the physician. He considered that the very first thing to do with a paralysed muscle was to relax it. Nerve grafting should be reserved for those cases in which neither all the muscle was paralysed nor all the irritability had disappeared.

Dr. L. G. GUTHRIE pointed out the drawbacks of taking the electrical reactions in a child. In those cases where the electrical reactions were found to be absent it did not follow that the reactions would not return.

Dr. F. E. BATTEN could not agree that galvanising should be recommended in the treatment of the disease. Where it was impossible to secure skilled massage they must educate the mother of the child to carry out the treatment and a considerable amount of good could be done by unskilled massage under proper instructions.

Mr. ROBERT JONES concurred with what Mr. Tubby had said and described some cases in which treatment by posture had been successful.

Dr. E. FARQUHAR BUZZARD said that they must not be content with the treatment applicable to those cases after the diagnosis had been made but must strive to discover some prophylactic measure.

Dr. F. J. POYNTON observed that the management of cases with limbs with isolated paralysed muscles was much more difficult than the management of those cases where the limb was generally wasted; in the last named the limb though it might be small was extremely useful afterwards.

After the PRESIDENT had pointed out that it was most desirable that the cause of the disease should be treated and had commented on the value of properly applied skilled massage,

Dr. RUSSELL replied.

SOCIETY OF ANÆSTHETISTS.

Spinal Anæsthesia.

A MEETING of this society was held on March 6th, Dr. R. J. PROBYN-WILLIAMS, the President, being in the chair.

Mr. H. PERCY DEAN read a paper on Spinal Anæsthesia. He referred to the rapid progress of this method on the continent, and pointed out that it was now four years since the discovery of stovaine by the French chemist Fournier, and that for three and a half years spinal anæsthesia with stovaine, novocaine, and similar bodies had been practised with very satisfactory results on a large scale abroad. Progress had not been nearly so rapid in this country, this being probably due to the conservative tendency of the English mind and to the generally excellent results of inhalation anæsthesia. In the great majority of cases the surgeon did not feel inclined to urge, nor did he feel justified in urging, a new method which, having the technique of spinal anæsthesia, was not free from the risk of what Paget had called "a surgical calamity." A layman interested in hospital work had objected that the sticking of a hollow needle into one's spinal column could not possibly be justified or compared with inhalation anæsthesia. Mr. Dean thought this objection of little weight if the effect on the lay mind were recalled of the first sight of a Clover's inhaler and other features of general anæsthesia. From his own experience he was convinced that in serious cases to which he had limited its employment the patient gained a great advantage, and he felt sure that the new method had come to stay and would gradually displace general anæsthesia in cases within its radius of action —viz., serious abdominal disease, injuries associated with shock, and operations accompanied by shock. Mr. Dean then considered the great advantages of the new method under the following headings. 1. The effect of spinal anæsthesia in preventing shock. He instanced two recent cases of his at the London Hospital which had impressed him with the remarkable freedom from surgical shock which the method conferred. 2. Certain grave abdominal diseases. He referred to grave general symptoms found in cases of peritonitis and intestinal obstruction. He had employed spinal anæsthesia in several cases of general septic peritonitis in which the typical symptoms of so-called peritonism were present. After the injection the patients had expressed themselves as feeling much better; indeed, one of the patients, a girl aged 16 years, volunteered the statement within seven minutes of the injection that she felt quite a different person. 3. Cases of general collapse in which a general anæsthetic would almost certainly have caused the death of the patient; cases in which there was general collapse of the heart and muscular system, together with general grave toxæmia. As a typical instance of this condition he mentioned a man, aged 52 years, admitted with a strangulated hernia of three days' duration. 4. Cases with marked bronchial and pulmonary symptoms. With spinal anæsthesia the condition of the chest was not affected. From his own experience Mr. Dean had come to the definite conclusion that it was the duty of the medical profession to give patients in any of these classes the advantage of spinal anæsthesia and that many lives would thereby be saved. In considering the important question, Should spinal anæsthesia be used as a routine method in all surgical cases? he quoted the experience of several patients who, having had general anæsthetics previously, all concurred in preferring spinal anæsthesia. Dealing with the statistics upon the subject Mr. Dean said that Dr. Gorton Thomas had collected over 5500 cases. Tuffier in Paris had used stovaine in 520 cases and with the exception of three cases in which it was necessary to repeat the dose had never failed to produce anæsthesia. Kummell reported 188 cases, in one-sixth of which he had failed to produce anæsthesia. The patients ranged from five to 60 years of age, 20 per cent. of cases showed some nausea during operation, and about 25 per cent. had headache after. Freund reported 209 cases, 87 per cent. good and 13 per cent. poor. Three-fourths of his cases were laparotomies. Deitz reported 360 cases treated with Billon's stovaine; there were 50 appendix operations, 11 gastro-enterostomies, one gastrectomy, one operation on the pancreas, and about 40 hernias. There were no deaths. Döderlin had 44 cases up to Jan. 1st, 1907, without a death. There was one failure to produce anæsthesia; some nausea during operation and post-operative headache in eight or nine cases; and in two cases there was slight muscular paralysis of the arm and neck lasting ten days. In Kroenig's clinique out of a series of 400 major gynæcological and abdominal operations a general anæsthetic was only given 35 times either at the request of the patient or the medical attendant. They used novocaine, alypin, tropacocaine, and stovaine and preferred the last. Tillmann had had perfect anæsthesia and no bad effects during or after operation. In a series of 500 laparotomies Kroenig had not encountered any complications of importance. Heineke and Lanekuren, after analysing 70 cases of novocaine and stovaine, came to the conclusion that after effects with novocaine were two and a half times more frequent than with stovaine. Mr. Dean himself had noticed less headache in recent cases in which he had used stovaine of a lower specific gravity than previously. He deliberately thought it was a very valuable method which would probably oust general anæsthetics in about five years.

Mr. A. L. FLEMMING asked whether Mr. Dean had used lumbar anæsthesia in Trendelenburg's position and what specific gravity he had employed; was it as low as 1·013?

Mr. H. W. ARMIT was interested to hear of Mr. Dean's success with stovaine. Some competent observers had reported failures, vomiting in 60 *per cent.*, and headache in 90 per cent. of cases. Mr. Armit then considered the various spinal anæsthetics from the pharmacological standpoint. Comparing their chemical constitution with their toxicity he found that cocaine contained two benzene rings, isopropionic acid, and several amino groups. Alypin only contained one benzene ring but was closely allied to cocaine in other ways and was found to be too toxic. Stovaine appeared to have advantages theoretically over the other two compounds and better clinical results bore out this consideration. Novocaine should be less toxic still but it appeared to be also less anæsthetic. Tropacaine theoretically should be the best of the series and Bier's and other German workers' experience confirmed this. Mr. Armit could not accept Kroenig's contention that varying the specific gravity determined at will the height of the anæsthesia.

Mr. L. H. MCGAVIN thought the method should be placed entirely in the hands of anæsthetists. He agreed with Mr. Dean that it would become the method of the future. There was no question that it did abolish shock. He had had no failures since he had given a second dose where one did not succeed. Mr. McGavin rather thought it caused tympanites. One of his patients vomited on the table. Most patients who had had chloroform previously preferred stovaine.

to all operating gynæcologists. The translation has been well carried out and the German text has been followed scrupulously.

Diagnosis of Organic Nervous Diseases. By CHRISTIAN A. HERTER, M.D., Professor of Pharmacology and Therapeutics at Columbia University, &c. Revised and enlarged by L. PIERCE CLARK, M.D., Visiting Neurologist to the Randall's Island Hospitals and Schools, New York, &c. London and New York: G. P. Putnam's Sons. 1907. Pp. 690. Price 12*s.* 6*d.* net.

THOUGH called elementary in character this book affords a very complete account of the diagnosis of nervous diseases. It opens with a chapter on the structure and functions of the nervous system which are considered in sufficient detail for the needs of the practical physician. Then follows a chapter on the symptomatology of nervous diseases, phenomena such as paralysis, contracture, convulsions, incoördination, and so forth, being considered in turn. Chapter III. deals with localisation of the lesion and Chapter IV. with recognition of the nature of the trouble. Chapter V. describes the different clinical types of disease and Chapter VI. deals with the diagnosis of organic from functional disorders. The seventh chapter is devoted to a description of the methods to be adopted for the examination of the patient, a subject which we should have expected to occupy an earlier position, as it is the basis of much that has preceded; and in the eighth and last chapter some illustrative cases are recorded as examples of the different maladies.

Our general impression of the book is distinctly favourable; it appears to have well merited the dignity of a second edition. The contents are clearly and well expressed and the information for the most part is accurate and up to date. The diagrams employed are useful and well adapted to illustrate the points desired, though one or two of the more ambitious illustrations from photographs are very poorly reproduced. The book should be useful to both students and practitioners who desire special guidance in the field of nervous disease.

Mental and Sick Nursing. By ROBERT JONES, M.D. Lond., F.R.C.P. Lond., F.R.C.S. Eng. London: The Scientific Press, Limited. 1907. Pp. 222.

IN this text-book Dr. Robert Jones has attempted the difficult task of writing a manual which shall be of service both to medical men and to nurses working in asylums. To write both for the medical and for the lay reader usually results in the work being too simple for the one or too technical for the other, but in this instance Dr. Jones is to be congratulated on producing a volume which will appeal to both classes. The medical officer whose duty it is to lecture to the nursing staff will find many valuable hints and suggestions in this small work.

In the opening chapters the author briefly describes the various parts of the nervous system and the different organs of the body. He then passes on to discuss mind and its attributes which are also dealt with as briefly as possible. Chapter VIII. is a very instructive one and deals with instincts and habits. Passing on to the description of the various forms of insanity Dr. Jones refers to the different classifications of mental disorder but advises that the one based on the symptoms is the most practical one for the nurse.

The duties of the mental nurse are well described. We do not quite agree with the author when he recommends in certain cases "vigorous outdoor exercise" for the maniacal patient; for unless he means by this the chronic maniacal dement we feel that the day for such treatment is past, for the whole tendency of the present time is to give to all persons suffering from recent excitement prolonged rest, preferably out of doors.

The description of insomnia and its treatment is good and instructive. Perhaps the best part of the book is that devoted to the various methods of treatment, such as massage, electricity, baths, and physical exercises. The account of the daily routine of the nurse's duties in the asylum is also a useful one and has the advantage of being written by one who has had wide experience in asylum administration.

The book is simply written and avoids all controversial subjects which divide the various schools of psychiatry, and in this the author is wise, as it prevents unnecessary confusion in the nurse's mind. Blank pages are interleaved which the nurse will find useful for notes of any lectures which she may attend. There is an excellent introduction by Sir William J. Collins, M.P. Altogether this small manual may be safely recommended to all those whose duty it is to tend and to nurse the insane.

Practical Dairy Bacteriology. Prepared for the use of Students, Dairymen, and all Interested in the Problems of the Relation of Milk to Public Health. By H. W. CONN, Ph.D., Professor of Biology of Wesleyan University and Bacteriologist to the State Board of Health of Connecticut. Illustrated. London: Kegan Paul, Trench, Trübner, and Co. 1907. Pp. 314. Price 6*s.* 6*d.*

THERE are few public health problems which are of greater interest than those connected with the milk-supply of a community and especially at the present time when various health authorities are seeking fresh powers for the control of farms and dairies and when the Government has promised to introduce a Bill for the better safeguarding of the milk of this country. A work dealing with some of these problems, written by an acknowledged authority, is therefore peculiarly welcome.

The book now reviewed is addressed to two classes of readers: to those interested in the problems arising in the dairy proper and to those interested in the problem of the relation of milk bacteria to the public health—that is, to the producer, distributer, and consumer of the milk. It is intended, on the one hand, to remove the lack of information of health officers as to the conditions and possibilities of the dairy and farm and, on the other hand, to remove the similar ignorance of the dairyman as to the necessities and demands of the public and thus to avoid the friction which is liable to arise between the producer and the inspector of the milk owing to a lack of comprehension of each other's difficulties. The author does not deal directly with administration but supplies information on which administrative action may be based. This is perhaps fortunate, for specific administrative regulations could hardly fail to be viewed from the standpoint of American conditions which differ widely from those of England.

When once the necessity of a pure and wholesome milk-supply is thoroughly realised, to satisfy these requirements is, as the author says, purely a matter of cost. It is here, however, that practical difficulties arise in avoiding on the one hand the ruin of the farmer and on the other such an increase in the cost of the purer milk that it may not be out of reach of the children of the poor. The improvement in the quality of the milk will of necessity be accompanied by some increase of the price. Already it is possible to get milk to which no exception can be taken but at a cost considerably greater than the average market price. There is no doubt, however, that much improvement might be effected without serious increase in the cost of production by the exercise of greater knowledge and intelligence on the part of the farmer and the dairyman and it is the aim of this book to supply the knowledge which would help to effect the desired improvement. One of the most interesting sections of the book deals with the value of the trained dairyman and it is shown that such a man will with the same apparatus and under the same conditions obtain milk containing only no reason for supposing the student to become suddenly susceptible to the precepts of surgical cleanliness by mere removal from the dissecting-room; and this surgical superstition was detrimental to the education of the student, both before and after qualification, and was further to the disadvantage of the patient both of the present and the future and reduced the surgeon's education towards the mechanic's grade. He hoped that those responsible for the surgical teaching of medical students and for the progress of their own surgical attainments would consider the matter in the light of common-sense rather than of sentiment. He made no attack on the methods of chemical surgical asepsis; he merely asked surgeons to have faith in the efficacy of their methods.—Mr. H. LITTLEWOOD said he felt inclined to agree with Dr. Grünbaum and welcomed his suggestions—Mr. R. LAWFORD KNAGGS, Mr. J. F. DOBSON, Mr. H. COLLINSON, Mr. H. DE C. WOODCOCK, and Dr. A. BRONNER also discussed the paper.—Dr. GRÜNBAUM replied.

Dr. L. A. ROWDEN showed a series of lantern slides illustrating the Diagnostic Uses of the X Rays.

Dr. A. L. WHITEHEAD showed Leber's apparatus for Transillumination of the Eyeball. The presence and extent of an intra-ocular sarcoma causing detachment of the retina without symptoms were demonstrated. A case of glaucoma with secondary cataract preventing an examination of the fundus was also shown. The absence of any growth within the eyeball was demonstrated, indicating that the glaucoma was of the simple primary form and not secondary to an intra-ocular tumour.

The PRESIDENT showed a specimen of about 1½ inches of Bone excised from the middle of the left clavicle five months after fracture to relieve pressure on the brachial plexus. The operation was successful.

Mr. DOBSON showed: 1. A patient from whom a Popliteal Aneurysm had been excised, together with the specimen. The popliteal vein was so firmly adherent to the sac of the aneurysm that it was necessary to divide it. The patient recovered without any embarrassment of the circulation. 2. A case in which Perforation of a Tuberculous Ulcer of the Ileum occurred with diffuse peritonitis and extensive disease of the mesenteric glands and adhesions of coils of intestine. The perforation was closed by suture, recovery ensuing.

Dr. J. STEWART showed a specimen containing 13 distinct Fibroids massed together which was removed from a patient, aged 45 years. She had retention of urine for ten days and obstruction of the bowels, vomiting, constipation, &c. Albumin was present in the urine. There was a mass impacted in the pelvis dissecting up the left broad ligament and firmly attached to the rectum. The patient made an uninterrupted recovery.

Mr. LITTLEWOOD showed a Kidney with Malignant Disease from a child nine months old.

Dr. W. H. MAXWELL TELLING showed a specimen of Dissecting Aneurysm of the Arch of the Aorta, causing death by rupture into the pericardium. There was a tear an inch long due to atheroma at the junction of the transverse and ascending portions of the arch. The aneurysm extended to the commencement of the thoracic aorta and four or five inches up the neck.

Mr. WOODCOCK showed a case of Myxo-sarcomata apparently primary in the breast. The interest in the case was in the very wide distribution of secondary subcutaneous nodules—present everywhere except in the limbs.

Cases and specimens were also shown by Dr. BRONNER, Dr. T. WARDROP GRIFFITH, Mr. LAWFORD KNAGGS, and Mr. B. G. A. MOYNIHAN.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Etiology of Plague in India.

A MEETING of this society was held on March 18th, Dr. JAMES RITCHIE, the President, being in the chair.

Lieutenant-Colonel W. B. BANNERMAN, director of the Bombay Bacteriological Laboratory, gave an account of "Recent Researches into the Etiology of Plague in India, with an account of the work of the recent Plague Commission appointed by the Government of India, whereby it is shown that the *rat flea is the cause of plague epidemics in that country*." After enumerating the *personnel* of the Commission he stated that Dr. C. J. Martin, director of the Lister Institute, satisfied himself that at Bombay only could the work of investigation be properly carried out. The present outbreak of plague in India commenced in the autumn of 1896. It was known that in the remote valleys of the Himalayas the disease was often present in sporadic form but it was regarded as an antiquarian curiosity and as one banished from the civilised country of Hindustan. A warning had been issued to the Government medical officers in the Madras Presidency to be on the outlook for plague as it had broken out in epidemic form in 1894 in China. Within a fortnight of the outbreak of the disease in India Mr. Haffkine was sent from Calcutta to Bombay and a committee of local medical men was convened to consider what should be done. It was soon seen that two types of the disease occurred—viz., the pneumonic, which was very contagious, and the bubonic and septicæmic, which was not communicated from one person to another. The hospital attendants or friends of the patients did not contract the disease unless a pneumonic case had occurred in the wards. Major Thomson even went the length of stating that one of the safest places during an epidemic of plague was the ward of a sanitary plague hospital, something more than mere contagion being necessary to develop the disease. The seasonal prevalence of the disease at different times soon became manifest. Thus the epidemic was present in Bombay during the early months of the year, while at Poona, only 80 miles distant, it was only prevalent during the autumn. As years passed it became noticeable that huts or houses became infected with plague and remained so even after the inhabitants had fled. Such rooms were found or suspected to be most dangerous at night. Cases of infection in health camps were traced to surreptitious visits paid to infected villages during the night; also after heavy rain which drove the people from the flimsy huts to their former abodes there were frequently outbursts of plague. Even empty houses became infective during the absence of their owners. The whole evidence went to prove that man-to-man infection was not the cause of the spread of plague. Very soon after the outbreak of plague in India commenced overwhelming evidence showed that the disease was due to rats. It was early noticed that houses in close proximity became infective, though their inhabitants, owing to caste or other prejudice, had no connexion with one another. In some of these cases rat-holes were found to communicate with different houses, or the house rats of India had easy access to dwellings through the flimsy roofs The epizootic preceded the epidemic and dead rats were looked upon as precursors of plague. The rule was, "When dead rats were seen clear out or be inoculated." Was the rat wholly responsible however? It was a common belief in India that infected clothes might spread plague both to men and to rats. Thus isolated villages previously free from plague became the seat of it on the importation of infected clothing into them. In such cases the disease first appeared amongst the rats and later amongst the inhabitants. Human beings were the carriers of infection into new areas remote from the focus of disease, but within towns and villages the case was far otherwise, rats being the means of dissemination. In India, Simond of the Pasteur Institute was the first to suggest that the flea was the carrier of the disease and was able to infect a healthy rat from a diseased one though actual contact was carefully avoided. The first plague commission, however, concluded "that suctorial insects do not come under consideration in connexion with the spread of plague." Captain W. Glen Liston, I.M.S., however, worked at this theory and by the time that the second plague commission arrived had been able to place the despised hypothesis in a new light. Two species of rats were found in Bombay: 1. Mus rattus, which was so tame that it has a place in India corresponding to the domestic cat of this country, living in every room and breeding in drawers or cupboards. 200 of these might be found dead in a single house. 2. Mus decumanus. This was not, strictly speaking, a house rat but burrowed in the ground and was found in thousands in the empty rain water drains and sewers. The latter variety was attacked at an earlier period and was more severely affected by plague than was the former. Infection to the human being was much more frequent from the mus rattus. Captain Liston found that the fleas of rats belonged to a different species from those of man. The common rat flea was the pulex cheopis and in the absence of rats this flea took to other animals and even to man. In March, 1903, the guinea-pigs in the Zoological Gardens in Bombay were attacked by plague and the animals sick or dead from the disease were found to be infested with fleas, reminiscent of the efforts of Silas Wegg. There is so much that is good in this little book that it is sure to run to a second edition, when we hope that some of the features of the last seven pages may be carefully revised or even omitted. Furniture polish and a cough mixture seem rather out of place amongst articles calculated to whet the appetite. But after all charity covers a multitude of sins, and the charitable object of this book encourages us to dwell rather on the general value than to seek for minor blemishes.

Merck's 1907 Index. Third edition.—This index is by no means a mere commercial compilation; it is really a valuable pharmaceutical encyclopædia giving the names and synonyms, formulæ, physical constants, solubilities, physiological effects, doses, and so forth of the chemicals and drugs used in medicine. We have found it to be a very useful source of reference for information in regard to more or less rare or novel drugs and allied preparations.

Thermo chemistry. By JULIUS THOMSEN, Emeritus Professor of Chemistry in the University of Copenhagen. Translated from the Danish by KATHARINE A. BURKE, B.Sc. Lond. London: Longmans, Green, and Co. 1908 Pp. 495. Price 9*s.*—Of recent years the study of thermochemistry has proceeded apace and results have been gained which have considerably developed our knowledge of the nature of chemical change. There has been no more ardent or successful worker in the field than Professor Thomsen of the University of Copenhagen, and the gratitude of all English students of chemical science is due to the translator of the volume before us for putting before them in clear terms the results of his labours and his views. His researches extended over a period of 20 years and the results were published during the years 1882 to 1886 in a four-volume work entitled "Thermo chemische Untersuchungen." The present work renders these results more accessible. As the translator points out, since the fourth volume of the original work was published in 1886 the conception of ionisation has been introduced into chemistry and therefore many of the statements which Professor Thomsen made are now generally interpreted by the light of that theory. This, however, does not detract from the value of the original work and "most of the numerical relationships shown by Professor Thomsen are independent of theory." The book is divided into four parts, the formation and properties of aqueous solutions being considered first, then the compounds of non-metals, next the compounds of metals with non-metals, and finally organic substances. Some idea of the complex machinery which the investigation of thermo-chemical problems involves may be gained from a drawing of the apparatus used for measuring the heat of formation of hydrogen chloride on page 190. The book may safely be assigned the position of a standard work on the subject.

Reminiscences. By GEORGE SAUNDERS, C.B., M.D. St. And., Deputy Inspector-General of Hospitals. London: James Nisbet and Co., Limited. 1907. Pp. 93. Price 1*s.* net.—Last week we recorded the latest honour which has been paid to the heroine of the Crimean war and we have now the opportunity of noticing the services to humanity which were given by another worker in that campaign of evil memory. Dr. Saunders, who was then surgeon to the 47th, and subsequently promoted staff-surgeon, well bore his share in a heart-breaking task and has some fresh tales to add to the horrible record of mismanagement in the Crimea. He subsequently was stationed at the Cape, and later in Asia, at Hong-Kong and Yokohama, where his work won the notice of the home Government. Of all these places Dr. Saunders has chatty reminiscences but his object in publishing them is that he may clearly testify in his eighty-fifth year to the faith that is in him. Very early in his professional career he became imbued with profound religious convictions and has since used constant efforts to impart to others the spiritual comfort which they have afforded him. In the army he became a notable evangelist, a voluntary work which must often have needed not a little moral courage, and when he retired from the service in 1871 he devoted himself to medical mission work amongst the poor, first in Liverpool and then in London, where he became the founder of the London Medical Mission.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

SYNTHETIC CAMPHOR (SCHERING).

(A. AND M. ZIMMERMANN, 3, LLOYD'S-AVENUE, LONDON, E.C.)

THIS beautifully white crystalline product represents a triumph of synthetic-chemistry. It is stated on very good authority that synthetic camphor is identical in its constitution and action with the natural product and that it can be employed for therapeutic purposes in exactly the same manner. Synthetic camphor, although it is only very slightly different from the natural product as regards its optical behaviour, yet is identical in all other physical and chemical properties.

SELF-RAISING FLOUR.

(SYDNEY W. BUSH AND SON, BATH)

An examination under the microscope as well as a simple chemical test sufficed to explain how this flour is "self-raising." It contains a small quantity of ingredients which interact on moistening, disengaging carbonic acid gas. The flour is of good quality and serves as an excellent material for the preparation of bread and pastry. From the quantity of mineral matter and proteins present it is evident that the flour contained the maximum amount of cereal nutritives.

CLOPIA (TEA).

(THE AGENT-GENERAL FOR THE CAPE OF GOOD HOPE, 98, VICTORIA-STREET, WESTMINSTER, LONDON, S.W.)

We are informed by the Trades Commissioner for the Cape of Good Hope that clopia, which is gathered from a bush growing wild in Cape Colony, is used as a substitute for tea. It is further stated that it has been found of value in cases of dyspepsia and rheumatism and by those with whom ordinary tea disagrees. We have submitted clopia to careful examination but we were not able to detect any alkaloid present. It yields some oil on suitable extraction and on treatment with boiling water a clear fluid having a colour like tea. On evaporation of this fluid a gummy residue is obtained amounting to 16·0 per cent. The mineral matter was 2·0 per cent. and contained alkaline salts. The protein amounted to 6·17 per cent. We have no knowledge of its use in practice but it is stated that clopia is liked in the colony and has been used with benefit according to the testimony of medical men there. It occurs in the form of needle-like spines of a brownish colour.

CARLSBAD SALTS AND WATERS.

(SOLE AGENTS: INGRAM AND ROYLE, LIMITED, EAST PAUL'S WHARF, 26, UPPER THAMES-STREET, LONDON, E.C.)

A point in distinct favour of the Carlsbad waters, or of the salts obtained by the evaporation of the waters, is that they show a constancy of composition which is of importance from the therapeutic point of view. We have examined the waters of Carlsbad and the salts more than once and on making a recent analysis the quantity of salts present showed little, if any, variation. The natural Carlsbad Sprudel salt is supplied in two forms, one a fine dry powder and the other in a crystallised state—that is to say, containing water of crystallisation. Of course, the quantity of salt in the dry powder it might infect rats in the new locality. The general conclusions were: (1) pneumonic plague was highly contagious, but being rare (less than 3 per cent. of all cases) played a very small part in the spread of the disease; (2) bubonic plague in man was not infectious and was entirely dependent on the disease in the rat; (3) the infection was conveyed from rat to rat and from rat to man solely by means of the rat flea; (4) a large majority of cases of plague occurred singly in houses, but where more than one case occurred in a room the attacks were usually nearly simultaneous; and (5) plague was usually conveyed from place to place by rat fleas brought by people in their baggage or on their persons.

Sir **THOMAS R. FRASER** desired to convey thanks to the whole of the Indian Medical Service for the good work which they had done and were doing. The duty of the first plague commission was to focus the then existing knowledge, but it did not embark on any scientific work. He alluded to the grossly insanitary conditions of the native houses which favoured the multiplication of rats and consequently of their parasites. He thought it would be well-nigh impossible to exterminate either rats or their fleas in India. Sir Thomas Fraser alluded to the marked immunity to the disease enjoyed by Europeans and stated that this was due to their better houses; even when attacked their mortality was only 22, as contrasted with from 90 to 98 per cent. of the natives. In the Glasgow epidemic of 1900 the disease was confined to the slums and rats were abundantly affected. The case mortality in Glasgow was about the same as it was in Europeans in India. The rat epidemic persisted for 18 months after the last case of plague in a human being had occurred in Glasgow.

Sir **ALEXANDER RUSSELL SIMPSON** and Dr. **ALLAN JAMIESON** took part in the discussion and Lieutenant-Colonel **BANNERMAN** replied.

Major **D. G. MARSHALL**, I.M.S. (retired), and Dr. **G. LOVELL GULLAND** described a case of Kala-Azar which had recently proved fatal in Edinburgh.

EDINBURGH OBSTETRICAL SOCIETY.

Transmission from the Mother to the Fœtus.—Frozen Sections.—The Operative Treatment of Displacements.

A MEETING of this society was held on March 11th, Professor **W. STEPHENSON** (Aberdeen), the President, being in the chair.

Dr. **JAMES LOCHEAD** read a paper on the Transmission of Nitrogenous Compounds from the Mother to the Fœtus. He said that experimental results showed an absence of altered proteins such as albumoses and peptone in the freshly obtained placenta of the sheep and an absence of any extracellular proteolytic ferment. Hence the placental action was not, as had been stated, analogous to that of the intestine. By the precipitin test egg albumin was shown to pass from the mother to the fœtus unchanged while ox serum did not. It was probable that the normal serum proteins also did not pass across the placenta as through a sieve but were transformed there and elaborated into products necessary for the growth of the fœtal tissues.

Dr. **A. H. FREELAND BARBOUR** read a paper on the Frozen Sections by Bumm and Blumreich and by Zangemeister, bearing on the question of the existence of a lower uterine segment. After a historical survey of the work done by means of frozen sections on the lower uterine segment during the last 30 years, Dr. Barbour proceeded to criticise the position taken up by Bumm and Blumreich as a result of their examination of frozen sections of the body of a primipara, aged 39 years, who died during the second stage of labour. Their views were that the so-called lower uterine segment was really formed by the stretched cervix and that the retraction ring was formed at the os internum, this being confirmed by microscopic examination. They therefore concluded that Barbour was wrong in the interpretation of his section published in 1890, that what he called stretched uterine wall was really stretched cervix, and that the membranes over this area, described as partly adhering and partly detached, were artificially adherent as the result of the freezing. In controverting this, Dr. Barbour pointed out that in Bumm and Blumreich's section the cervix posteriorly was 3·7 inches in length, as against 1·3 inches in his own, and that there was a corresponding difference in the thickness from 1 to 2 millimetres as against 4½ millimetres. He exhibited micro-photographs from his own case showing quite clearly that the decidua and chorion were actually growing on area between the retraction ring and the upper limit of t cervix as determined by the presence of typical cervi glands in the area in question. He attributed differences in the two sections to the different ages of patients and to probable differences in the amount of openin up of the cervix before labour began. Finally, he the lower uterine segment as "that part of the uterus must be converted into a canal so as to allow the fœtus pass." This corresponded to rather less than a fourth of total cavity of the uterus. This part of the uterus might pressure of its contents have its muscular bundles opened so that it contracted less efficiently when labour set Whether the retraction ring formed at the os internum, as i did in some cases, or higher up would depend on the c tractile efficiency of the musculature. The section y Zangemeister was from a case of rupture of the uterus. As the sections were coronal the peritoneal relations were well seen, the greater part of the rupture being lateral extra-peritoneal; the peritoneum was torn through only for a small area posteriorly.

Dr. **W. E. FOTHERGILL** (Manchester) read a paper on the Operative Treatment of Downward and Backward Displacements. The pelvic viscera, he considered, were mainly supported by the denser portions of the parametric, paravaginal, and paravesical connective tissue; in other words, by the sheath of the blood-vessels and the lymphatics of the uterus, vagina, and bladder. The one constant and essential factor in the causation of prolapse was relaxation and elongation of these perivascular sheaths. Insufficiency of the pelvic diaphragm and perineum, increased intra-abdominal pressure, and increased weight of the uterus were mere separable accidents which did not occur in all cases of prolapse. Relaxation of the whole lateral mass of perivascular tissue caused classical prolapse, but relaxation of the lower portion alone produced cystocele and vaginal prolapse, while relaxation of the parametrium alone permitted the occurrence of pure retroversion. The ideal surgical treatment of prolapse would be shortening of the whole lateral mass of perivascular tissue, but the best that could actually be done in this direction was the performance of anterior colporrhaphy in such a manner as to bring together in the middle line behind the bladder and in front of the cervix and vagina the tissues which previously lay at the sides of the cervix and vagina. As a uterus which had once been loosened would always be loose, this measure should be supplemented by posterior colporrhaphy and perineorrhaphy. In the worst cases ventro-fixation should also be done in such a manner as to secure firm union between the anterior surface of the uterus and the posterior surface of the recti. Peritoneal adhesions were inefficient for this purpose, as were all operations depending upon the use of the round ligaments. These operations, however, were suitable for those cases of retroversion, uncomplicated by prolapse, in which operative treatment was required.—Sir **J. HALLIDAY CROOM**, Sir **A. R. SIMPSON**, Dr. **R. P. RANKEN LYLE**, and Dr. **BARBOUR** took part in the discussion.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held at Bolingbroke Hospital on March 11th, Dr. A. Dumville Roe, the President, being in the chair.—Dr. T. N. Kelynack read a paper on Recent Researches Regarding the Pathology of Alcoholism. Alcoholism, he said, was a many-sided medicosociological problem into which investigation was being made in many varied methods but only strictly logical and scientific methods were of any value. Dealing with the evolution of the alcoholic, he mentioned the view of Dr. G. Archdall Reid that the human desire for stimulant is innate; the theory of the presence of "hormones" in the blood; that natural selection tends to the elimination of the alcoholic. The rôle of heredity in the causation of alcoholism was discussed, it being held that it was indisputably established that the offspring of the alcoholic were lacking in the elements which make for sound mental balance and vigorous bodily life, and Dr. F. W. Mott's conclusions on the interdependence of alcohol and insanity being quoted. The effect of environment was next considered and Dr. Kelynack briefly reviewed the laboratory work of Kraepelin, Mott, and others, offering some suggestive lines on which family practitioners might investigate the causes which conduce to alcoholism and the relationships between it and other diseases. The chief measure of prevention lay in the education of the child and next in importance was an

THE LANCET.

LONDON: SATURDAY, MARCH 28, 1908.

The Humane Slaughtering of Animals.

A CIRCULAR which is dated March 20th has been issued by the Local Government Board on the humane slaughtering of animals. It is addressed to the councils of boroughs and of urban and rural districts, and calls their attention to certain recommendations made by the committee appointed by the Admiralty to investigate this matter. These recommendations were published in 1904 and, recognising their importance, the Admiralty built at the dockyards of Chatham a model slaughter-house where the advice given is actually put into practice. Apparently, however, this example has not been of much service, since to-day these facts have to be recalled by the circular which the Local Government Board has sent to the local authorities. It is, indeed, somewhat discouraging to find that, in spite of all that has been written and said during the last three years concerning the dangerous and unsatisfactory condition of the meat-supply in this country, so few improvements have been effected. The circular now before us deals only with the question of humane slaughtering, though in actual practice public health and the kind and considerate treatment of animals are inevitably and intimately associated. The abolition of private slaughter-houses is desirable because they cannot be efficiently inspected and diseased meat is therefore less likely to be discovered, seized, and destroyed, whilst cruelty is less likely to be observed and checked. Thus the two interests, the claims of humanity and the claims of hygiene, go hand in hand.

There is, however, a difficulty—an important point where the two interests may fail to harmonise. From the sanitary point of view, which means the securing of ample room, light, air, and cleanliness, and the greatest possible facilities for inspection and control, the slaughter-hall is preferred to small and separate compartments. All the model abattoirs are built on this principle and not only is sanitation in every respect more easily maintained but the cruel treatment of any animal can at once be seen. This, of course, cannot be the case where there are only small private slaughter-houses in different parts of the town or even where a large public abattoir is divided up into small slaughter-chambers. But the circular raises a difficulty, for it says that the animals about to be killed must not see into the slaughter-house. In that case the slaughter-hall would cease to be a place for slaughter, and this is the actual condition of things at the model abattoir built in the Chatham dockyards. At Chatham the animals are brought to a place just outside the walls of the great hall. Here they are felled and then only is a sliding door opened and with the aid of ropes and pulleys the carcass is promptly drawn into the large hall. But the number of cattle killed there is very small and it would not be possible to kill more than two horned animals at the same time. If, however, it was necessary to kill 20 or 30 cattle at the same time, an equal number of sliding doors and pulley arrangements would be required and this might prove somewhat complicated. As a rule the animal is killed on the spot where its carcass is to be cut open and converted into meat. But when this is done in a large slaughter-hall the animals must see something of what is going on around them. Yet the circular says that the animals should, as far as possible, not be placed in contact with the sights and smells of the slaughter-house. Certainly, the waiting pens where the cattle are resting, perhaps for some days, should be well away from any smell or sight of blood, hides, offal, or anything likely to cause alarm. But at the last moment, in what are considered the best abattoirs in the world, the animals are killed in the slaughter-hall itself and not outside. The Admiralty committee in its report, and the passage is quoted in the Local Government Board circular, says: "There is no point which the committee have more carefully investigated than the question as to whether animals do or do not suffer fear from this contact, and the evidence of those best qualified to judge is so conflicting that no absolute verdict can be given." The report adds that the cattle frequently show great reluctance to enter the slaughter-chamber. Undoubtedly this is so where there is a ghastly display of blood, offal, and carcasses. But in a model slaughter-hall the blood is washed away as fast as it is spilt and the whole place is so light, bright, fresh, and clean that the animals are not so likely to be alarmed, and we are not aware that any complaints have been made on this score. On the other hand, the advantages of the large slaughter-hall system are so positive in every other respect that it would be regrettable if the effect of the circular just issued was to delay the construction of abattoirs on the ground that animals brought into a large slaughter-hall cannot be prevented from seeing each other. At the same time, short of delaying reform that is urgently needed, it would be an excellent thing to give the animals, as suggested in the circular, the advantage of the doubt and to slaughter them outside the walls of the great hall, as is actually done at Chatham.

Wherever the animals are killed, it is absolutely imperative if there is to be no cruelty that none but well-trained and highly skilled slaughterers should be allowed to kill. That is another reason for abolishing private slaughter-houses and concentrating the whole business in a public abattoir. Therefore, and very properly, the circular urges that "none but licensed men shall be employed in or about slaughter-houses," and we are of opinion that such licences should be withdrawn in the event of the holders being found guilty of negligence or cruelty. At present there is no law by which local authorities can prohibit a person who does not hold a licence from slaughtering. But, of course, if there was a public abattoir the authorities could refuse to employ unskilled and unqualified slaughterers. In this country, moreover, the examination of the meat put on the market is not at present carried out with anything like the care and thoroughness which are exercised in Germany. The public abattoirs in England, as in Germany, should therefore be utilised as theoretical and in the discussion: Dr. Braithwaite, Dr. E. N. Cunliffe, Dr. F. Craven Moore, Dr. E. S. Reynolds, Professor J. Lorrain Smith, Dr. Thompson, and Dr. A. T. Wilkinson.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 18th, Dr. A. Fulton being in the chair.—Dr. A. O. Reid showed a man, aged 32 years, who had come under notice two years previously with a large Tumour occupying nearly the whole area of the upper half of the abdomen and with dyspeptic symptoms. No satisfactory diagnosis had as yet been arrived at.—Mr. W. M. Willis showed a woman, aged 61 years, with a large Cystic Swelling in one breast, first noticed eight or nine months ago.—Dr. F. H. Jacob opened a discussion on the Feeding of Infants. After tracing the digestive difficulties which might arise in breast-fed babies Dr. Jacob dealt with some of the problems which had to be met in artificial feeding. Vomiting often arose from the curd of cow's milk but might on the other hand be due to an excess of fat. Some children did not thrive until they were given mercury, and warmth was important for all. When cow's milk did not agree with a child it was an interesting problem as to what other food should be tried in its place. Another question open to discussion was how soon starchy food might be begun, and the same applied to eggs. The broad lines of diet in infantile diseases were also sketched.—The discussion was continued by Dr. Fulton, Dr. W. Tibbles, Dr. J. S. Bolton, Dr. J. H. Thompson, Dr. J. Watson, Mr. R. E. P. Squibbs, Mr. A. R. Tweedie, Dr. J. W. Scott, Mr. T. Geraty, Mr. C. J. S. Dismorr, Dr. W. O. O. Kirkwood, Dr. A. J. Sharp, and Dr. J. A. O. Briggs, and Dr. Jacob replied.

Reviews and Notices of Books

Pathology, General and Special, for Students of Medicine. By R. TANNER HEWLETT, M.D. Lond., F.R.C.P. Lond., D.P.H. R.O.P.S. Lond., Professor of General Pathology and Bacteriology in King's College, London; Lecturer on Bacteriology, London School of Tropical Medicine; Physician to the Seamen's Hospital, Greenwich; Examiner in Pathology, University of Aberdeen; Examiner in Tropical Medicine, University of London. Second edition. London: J. and A. Churchill. 1907. Pp. 585. Price 10*s*. 6*d*. net.

THE appearance of a second edition of Professor Hewlett's book on pathology within a year of the issue of the first shows that it has met with the recognition which it deserves. As a convenient short handbook of the subject it supplies a distinct want. A great deal of recent work is succinctly summarised and incorporated, and, as we pointed out in our review of the first edition, it is surprising how much information is included within so small compass and yet in a form easy to grasp. Professor Hewlett is especially to be commended for the clear way in which he discusses matters which are controversial and for the impartial manner in which he presents theories and criticises them.

In general outline the present edition conforms to that of the previous one but certain additions have been made, notably in the section dealing with heredity, in which some reference is made to the principles of Mendelism. The chapter on neoplasms has also been extended and forms a very clear summary of the general features of new growths. The discussion of the etiology of tumours is clear and affords a valuable *résumé* of the various views current on this subject. Arterio-sclerosis also is considered in greater detail in this edition and reference is made to recent work on the experimental production of arterio-sclerosis. Medial sclerosis of the Moenckeberg type is differentiated from atheroma which is defined as "a localised, patchy, fibro-plastic infiltration of the intima," and this in turn is separated from diffuse intimal sclerosis. Additions have also been made to the sections dealing with the degenerations and infiltrations and to those devoted to inflammation, the infections, and the heart. The chapter on the pathology of the female generative organs has been practically rewritten by Dr. Frank E. Taylor and contains short accounts of the various morbid conditions which are usually met with in these organs. A section is devoted to the toxæmia of pregnancy and this, though brief, is to the point.

The consideration of the special pathology of the various systems and organs is not as full as that of the principles of general pathology, although in most cases the accounts given are thoroughly practical and intelligible; in a few, however, there is little more than an enumeration of the various morbid conditions with brief explanatory notes, but in these, as a rule, the conditions have been described under the general description of the morbid processes.

We are of opinion that Professor Hewlett's book is a useful manual for those wishing to obtain a critical presentation of the state of our knowledge in regard to the pathology of disease in convenient form. The book is well produced and is illustrated by a number of reproductions of microphotographs principally of microscopical specimens.

The Technique of Vagino-peritoneal Operations. By Professor E. WERTHEIM and Dr. TH. MICHOLITSCH. Translated into English by CUTHBERT LOCKYER, M.D., B.S. Lond., M.R.C.P. Lond., F.R.C.S. Eng. With 138 illustrations. London: Macmillan and Co., Limited. 1907. Pp. 323. Price 25*s* net.

THERE can be no question that some of the most difficult operations in gynæcological surgery are those which are undertaken through the vagina. The difficulty of obtaining free access to the field of operation and the small space often in which the necessary manipulations have to be carried out may render these operations extremely difficult and tedious. This manual by Professor Wertheim and Dr. Th. Micholitsch is the only systematic work which has appeared on this subject and Dr. Cuthbert Lockyer has conferred a considerable benefit upon English gynæcologists by undertaking its translation. The book, we need hardly inform our readers, is an exceedingly good one and is well worthy of the very high reputation of its authors. The illustrations are admirable and the descriptions appended are concise, clear, and trustworthy. The figures are from photographs taken from the cadaver after splitting the symphysis pubis so as to render the field of operation readily accessible for photography. This must be remembered by the young surgeon who consults the book, since on looking at the pictures many of these operations appear to be very easy and to entail no great amount of manual dexterity; whereas on the living subject this is often far from being the case, and it is necessary, therefore, for the reader not to be misled by the clearness of the drawings. The manner in which the various operations have been shown on the cadaver is most ingenious and must have entailed a considerable amount of trouble.

The directions given as to the best manner of carrying out the different procedures are extremely good and the successive steps to each are described in detail. All the operations which can be carried out through the vagina and which involve opening the peritoneal cavity are discussed in turn and no one could help receiving much information and many useful hints from a study of this work. The main principles to be followed are clearly set out and we notice amongst others that the great advantage of always opening the anterior fornix of the vagina rather than the posterior is laid stress upon. There can be no doubt as to the truth of the authors' statement that in this way all the pelvic structures, even those lying behind the uterus, can be best reached and dealt with most readily.

With the reservation we have made—namely, that the reader must remember carefully that the symphysis pubis has been split and that the photographs have been made up, so to speak—this work should prove of the greatest assistance defective) with short and repeated terms of imprisonment as the only means of dealing with them. If any English statute gave the State power to deal properly with these persons much might be said for insistence upon the work being carried out by the central authority; but Parliament saw fit to lay equal onus upon State and local funds and the action of the London County Council in practically refusing to make adequate provision for the inebriates in its jurisdiction is blocking the progress of a movement which has been demanded by experience, science, and humanity. This action of the Council, in regard to London inebriates, certainly saves something like £6000 a year in cash, but the economy is only on the surface as everyone who knows what is the cost to the community of dealing with drunkards upon the old-fashioned lines is perfectly aware. It is to be hoped that some compromise may be effected or some argument be brought to bear upon the London County Council before the inevitable evils of its action begin to be felt.

The Degree of Personal Communicability of Pulmonary Tuberculosis.

THE problems involved in the etiology and modes of infection of pulmonary tuberculosis are of such complexity and of so debateable a character that, in spite of the most assiduous and critical attention which has been devoted to them from very various standpoints by many painstaking observers, they are exceedingly difficult to solve and at the present time great confusion exists in regard to many of them. Apart from the question of the channels of infection, whether preponderatingly alimentary or respiratory, which has received so much notice within recent years, one of the most vexed of these problems is that concerned with the determination of the degree of infectiousness of pulmonary tuberculosis from person to person. The question is one of the greatest practical importance from the point of view of preventive measures directed to lessening the incidence of that disease and also from that of the attitude of the public generally towards the consumptive person. We have on more than one occasion deprecated the tendency to treat the sufferers from this disease as pariahs sedulously to be avoided, which the current views as to the spread of pulmonary tuberculosis have fostered with a not inconsiderable section of even the more thoughtful members of the public, thereby inflicting needless pain and suffering upon a class of person already sorely stricken in the battle of life.

In the interesting report on "Sanatoria for Consumption and certain other Aspects of the Tuberculous Question," prepared by Dr. H. TIMBRELL BULSTRODE and published as a supplement to the twenty-fifth annual report of the Local Government Board, which we have already noticed in a leading article,[1] a chapter of considerable interest is devoted to a consideration of "the degree of personal communicability of pulmonary tuberculosis." The evidence on this subject, which has been carefully collated and arranged by Dr. BULSTRODE, shows how difficult it is with the data at present available to form any definite judgment in this connexion and also to what extent the evidence adduced both for and against the main thesis is open to criticism. The statistics most frequently appealed to in order to throw light upon this question are those of the staff and attendants at institutions specially set apart for the care of consumptives and those of the apparent infection between husband and wife. In regard to the statistics derived from the incidence of tuberculous disease of the lungs in officials at hospitals or other institutions for the care of consumptives various statements are on record. There are in the first place the well-known statistics of Dr. C. THEODORE WILLIAMS of the hospital attendants at the Brompton Hospital for Consumption, which appeared to show that the incidence of the disease was not greater than the average among the civil population of a town even before the days of special precautions. Dr. BULSTRODE quotes other statistics to the same effect, such as those of Falkenstein, Görbersdorf, the Friedrichsheim Hospital at Berlin, and various other institutions. He refers to the criticisms of CORNET who is an advanced contagionist (this is Dr. BULSTRODE'S not over happy term) and thinks that the figures are too small and that the observations extended over too short a period to allow of definite conclusions being drawn. CORNET also alludes to the experience of certain Prussian nursing orders which appears to support the hypothesis of contagion. The figures derived from these sources have in turn been subjected to a careful mathematical analysis by Dr. W. H. HAMER at Dr. BULSTRODE'S suggestion and prove to be far from convincing or free from objection. For comparison, some figures in regard to the infectivity of other diseases generally believed to be directly infective, such as enteric fever, scarlet fever, typhus fever, and diphtheria as illustrated by the staffs of fever hospitals, are quoted and prove to be far more suggestive of direct infection. It might have been supposed that in regard to the transmission of pulmonary tuberculosis between husband and wife there would be a ready means of obtaining most valuable direct evidence upon the point at issue. It must be confessed, however, that whereas the consideration of individual instances would seem to be very highly suggestive of direct personal infection, yet when general statistics are reviewed in regard to this matter they are far from conclusive and cannot be said to afford strong evidence of contagion.

Many of the sanitarian authorities of this country, notably Dr. A. NEWSHOLME and Dr. J. NIVEN, to whose work frequent reference is made in Dr. BULSTRODE'S report, have devoted considerable attention to the influence of association with the subjects of known tuberculous disease as a factor in the spread of that disease. Dr. NEWSHOLME, who attaches great importance to case to case infection, suggests that the segregation of patients in workhouses and infirmaries has been an important factor in producing the fall in the death-rate from pulmonary tuberculosis which has occurred in recent years. This contention has been adversely criticised by many observers, including Dr. NIVEN. Dr. BULSTRODE summarises these objections in a very able manner. From the statistical point of view, therefore, the evidence of personal contagion in pulmonary tuberculosis is obviously most unsatisfactory and the conclusion of Sir HUGH BEEVOR which is quoted in the report to the effect one-fifth of the impurity found in that obtained by the untrained, but not unskilled, worker.

---

[1] THE LANCET, Feb. 1st, 1908, p. 385.

After a brief but accurate account of the morphology, classification, and vital conditions of bacteria there is a short account of the normal and abnormal types of bacteria found in milk, their sources, and the usual course of their multiplication. The next chapter on disease germs in milk is of more interest to medical readers and the subject is treated under the two heads of infections derived directly from the cow and indirectly from external sources. A clear account of the relation of the bacillus tuberculosis to the milk-supply is given and the author concludes with an unusually definite expression of opinion as to the futility of any system of inspection or analysis, whether chemical or bacteriological, to prevent danger arising from the tubercle bacillus. "Until a law requires the universal testing of all cattle (with tuberculin) and the immediate slaughter of all reacting animals any public dairy inspection will be futile in this respect." We should welcome more such definite expressions of the author's opinions; as a rule the subjects are treated with judicial impartiality and the reader is left to draw his own conclusions.

Dairy methods are next treated and the importance of grooming the cattle, moistening the udder when milking, and milking in a special room is insisted upon and graphic representations are given to show the improvement in the quality of the milk which follows on the adoption of these various precautions. In writing of the treatment of milk for the market the author appears to favour the pasteurisation of the supply and this is developed in the interesting section on Public Problems into the statement that "the sole practical method of assurance that the milk should contain no specific disease germs is by adopting pasteurisation or sterilisation." In this section also the author discusses the use of "standards of impurity" and dairy inspection, chiefly to show the difficulties which surround them, and finally, though with reluctance, adopts the idea of compulsory pasteurisation of the milk-supply. This idea has not been accepted with favour in England on the ground that it would lead to dirt and carelessness on the part of the farmer or the dairyman and would cause him to sink back into the slovenliness from which he has been slowly roused.

The transportation of milk is in England a thorny question but there is no doubt that the railway companies will have to provide facilities for cold storage during transit and the farmers will have to learn the necessity of immediately cooling their milk. "No dairy is properly equipped unless it has an ice-supply." It cannot be said of this country, as the author says of America, that "milk-handlers have learned to use ice freely." The next portion of the book is of more especial interest to the dairyman and is concerned with butter-making and cheese ripening. Finally, in the second part of the book there is a practical laboratory course of dairy bacteriology, including the examination, cultivation, and enumeration of milk bacteria.

There is no doubt that the book will be of value to those for whom it was designed and that it treats its subject very lucidly. The book contains a few misprints but is clearly printed and satisfactorily illustrated.

LIBRARY TABLE.

Technique Chirurgicale Journalière au lit du Malade. (*A Handbook of Clinical Methods in Surgery*). By Dr. A. BESSON, Maître de Conférences in the Faculty of Medicine at Lille. Second edition, revised and enlarged. Paris: Vigot Frères. 1908. Pp. 249, with 28 figures. Price 3 francs.—This is a capital little book of a kind familiar to English medical students. We will not go so far as to say that it is better than similar publications in our own language but it certainly challenges comparison with the best of them. Dr. Besson writes clearly and treats of all such matters as splints, plasters, injections, lavages, instruments, sutures, and so on, in a really instructive manner. The main headings are alphabetically arranged and the book opens with a section on anæsthetics, in which 70 pages are devoted to general and 16 pages to local anæsthesia. The chapter on chloroform is excellent, though we cannot agree with the statement on p. 23, "Tous les appareils, masques, etc., sont parfaitement inutiles," which indeed seems to be contradicted later, as eight pages are devoted to describing some of the "appareils" devised for its administration. It is interesting to read: "En obstétrique on emploie la chloroforme à la reine (Victoria d'Angleterre)." Tests for the purity of chloroform are given. With regard to ether the author says, "The student and practitioner will quite certainly have to give chloroform more or less frequently, but they may go through their whole careers without ever once giving ether," a statement which does not indicate that anæsthesia as set forth is sufficiently dealt with or presented in the wider range adopted in England. The technique of anæsthesia by scopolomaine, cocaine, and eucaine (by lumbar puncture and local) is described, though we have not noticed any reference to the adrenalin combination with the last drug. We disagree with the author when he prefers to make plaster splints by pouring the water on to the plaster instead of *vice versâ*. In a useful section on the technique of Bier's hyperæmic treatment stress is laid on the leucocytic theory of its action, but opsonins are not even mentioned. But the book contains a solid mass of useful information.

Medical Laboratory Methods and Tests. By HERBERT FRENCH, M.A., M.D. Oxon., F.R.C.P. Lond., Assistant Physician to Guy's Hospital, &c. Second edition. London: Baillière, Tindall, and Cox. 1908. Pp. 175. Price 5*s.* net.—We gladly welcome a second edition of Dr. French's excellent little work which gained such favourable notice when it first appeared nearly four years ago. The general get-up of the book is little altered, though the use of black type for headings in place of italics makes reference easier. Some expansion in size has taken place, new methods being included—as, for example, those for opsonic investigations. The illustrations have also for the most part been replaced by more artistic, though not necessarily more useful, pictures. We are a little surprised that the silhouette figure of hydatid booklets still remains, as it gives a false impression of these transparent little objects. Why also in the description of pancreatic cyst fluid is no mention made of the possible presence of a fat-splitting ferment? A number of coloured illustrations have been added which we do not altogether welcome, as we feel that the increased price of the book is probably due to their inclusion, and on the whole we think that the cheapness of the original edition was a merit which is hardly compensated by these more showy adornments. The contents of the book are, however, admirable and it continues to form a most useful handbook, almost indispensable to students and practitioners.

The King's College Hospital Book of Cooking Recipes. London: Longmans, Green, and Co. 1907. Pp. 272. Price 1*s.*—This unpretentious little book consists of a collection of recipes contributed by friends of the hospital and it is published in aid of the fund for the removal of the hospital to South London. Those responsible for the compilation modestly hope that as cookery books go this one will be found to be no bad shillingsworth. Many of the directions in the book have been submitted to the test of trial with highly satisfactory results. They have been found to be sufficiently clear for general guidance and in many instances the outcome has been cordially approved. Although the general style is devoid of literary grace we have discovered one recipe cast into some 14 lines of verse, rather

FORESTRY AND HYGIENE.

"Alexander von Humboldt," writes an Italian correspondent, "measured the decline of a nation's vitality by the destruction of its woods, and certainly it is among those nationalities of modern Europe that are the mere *simulacra* of their mighty past that the coincidence pointed out by the German philosopher finds aptest illustration. Greece, Italy, Spain in the day now passing look wistfully back to their former selves, now well-nigh unrecognisable by the denudation of what was once their ornament and pride. Mainland and island in the modern Hellenic State are, in respect of their sylvan covering, at once 'naked and ashamed.' Italy can no longer quote with anything but self-reproach the 'golden lines' of Virgil—

> 'Sed neque Medorum silvae, ditissima terra,
> Laudibus Italiae certent';

and as for Spain it is common knowledge that the majestic oak forests of which Martial sings avenged themselves for their destruction by the ruin of her mercantile marine. Even in countries less backward the reckless tree-felling uncompensated by collateral tree-planting is engaging the serious thought of the legislature—France having just, through her Minister of Agriculture, introduced a Bill to check the wood-cutting 'frenzy' which, in the words of one of her most prominent publicists, 'is now assuming disastrous proportions.' But it is in Italy that this 'frenzy' is most chronic and at intervals most acute. 'We are now,' says an '*ingegnere forestale*' (forest engineer), 'consuming in the shape of fuel 13,000,000 cubic metres of timber in excess of the annual production of our woods and plantations, and this although in 1906 we imported timber from Austria-Hungary to the value of 90,000,000 francs. In the case of the chestnut alone we are like a man who with the income of 7000 francs (£280) spends 10,000 francs (£400).' The poor chestnut! Who that knows Italy can have failed to admire the beauty of that classic tree, whether he has paced, as Macaulay sings,—

> 'In April's ivory moonlight
> Beneath the chestnut shade,'

or watched on picturesque uplands the steady growth and output of the 'castaneae nuces,' on which the hardy peasantry are as dependent for food as the Irish on the potato? But now its extinction is seemingly but a question of time, so heavy is the yearly toll which it pays to the wood-cutter who has to meet the ever-increasing demands of the tanning industry, insatiable for the gallic and tannic acid which it yields. In the meteorological sphere the destruction of the woods and forests—in other words, the reduction of the hill-sides and low-lying plains to so much prairie—is scarcely less to be deplored. On the testimony of the medical climatologist the health—to say nothing of the amenity—of whole provinces has been changed for the worse, say, within the last 50 or 60 years by the disappearance of the timber, and this quite apart from the progressive devastation wrought by the summer hail storms and the autumn flood. Alternations of temperature, at once violent and rapid, are experienced in regions

> 'Ver ubi longum tepidasque præbet
> *Jupiter brumas*,'

in days long subsequent to those of Horace, alternations telling severely on the population and still more on the visitor from abroad and compromising the fair name of Italy as a winter or spring resort for the invalid. All this in its economic, industrial, hygienic, even artistic significance is borne in upon contemporary Italy with a force and an insistence that press from her heart a cry of alarm and inspires legislation which would be salutary if its execution were as effective as its inspiration is sound. But she is only beginning to realise the complexity as well as the magnitude of the task before her. To begin with, she has to create and to foster a more efficient school of forestry than she at present can boast of, that at Vallombrosa, now about to be transferred on a larger scale and with better equipment to Florence, being still her only counterpart to the splendidly appointed schools of Germany and France. Again, she has to organise and to remunerate her army of '*ispettori forestali*' (forest inspectors) much more intelligently and liberally than hitherto if her laws for the prevention of unauthorised tree-felling are not to be more 'honoured in the breach than in the observance.' The 'situation,' in fact, must be faced and met with all the machinery, professional and expert, at her command if she is to save herself from disaster before it becomes irremediable. It is to her medical Minister of Agriculture, the Senator Guido Baccelli, that she hitherto owes her best legislation *ad hoc*. It is to the profession of which he is the titular head that Italians are looking most hopefully for the ultimate solution of a problem fraught with momentous issues for many interests, not least for that of the 'salus populi.'"

CHILDREN AS THE STOCK-IN-TRADE OF ORGAN-GRINDERS AND OTHER MENDICANTS.

TWO Italians, Vittorio Violo and Elizabeth Pelosi, were recently sentenced at Marlborough-street police court to one month's imprisonment without hard labour, and recommended for subsequent deportation, for begging in the streets and for using Antonio Pelosi, the two-year-old child of the female defendant, as a means of exciting compassion and obtaining alms. The begging was of the type with which Londoners have for some years been familiar, two foreigners, one male and one female, a baby, and an organ, the impression successfully produced, no doubt, in the minds of benevolent passers-by being that a married couple in poor circumstances are endeavouring to support themselves and their offspring by producing music. In the case before the magistrate it was proved that the man was hired by the woman at a wage of 1*s.* 2*d.* per diem to turn the handle of the organ and that she was a married woman deserted by her husband who had left her with five children. The child taken with her was her own but inquiry showed that such is by no means always the case. Evidence was given by the police that children are frequently hired in order that they may be taken out with organs, that the usual rate of payment for them is 6*d.* a day, and that they have practically supplanted monkeys for the purpose. The sum of £1 4*s.* in silver and bronze was found upon Violo. With regard to the "music" produced by persons of this class opinions seem to differ, but it is obvious that it may often become a nuisance. Presumably the "hurdy-gurdy" player with whom those now middle-aged were familiar in their childhood imported an instrument more or less peculiar to his country and was at first regarded with interest as a foreign performer who was amusing to children and comparatively innocuous. The piano-organ has nothing whatever to do with the country of the persons who play it and is simply a commercial speculation of its manufacturer and of its owner, the latter of whom makes his profit by letting it to the men and women who use it as a means of begging. To the extent to which it adds to the noise and unrest of London life it is prejudicial to the health of the community, but no doubt because it is heard by many more people at a time it brings in heavier contributions of coppers than the hurdy-gurdy ever could. Its use, however, even in those by-streets where children dance to its strains, is intrinsically for the purpose of begging, and for no other. With regard to the infants dragged round with it, usually in baskets attached to its carriage, whether these belong to is greater owing to the absence of water of crystallisation. The dry powder contains about 46 per cent. of sulphate of sodium (with some sulphate of potassium), about 17 per cent. of chloride of sodium, and a little over 30 per cent. of bicarbonate of sodium. The water of the "Sprudel" contained, we found, a total of 52·70 grammes of salts per litre, the water of the Mühlbrunnen 52·30 grammes, and the water of the Schlossbrunnen, 54·0 grammes. The value of a course of Carlsbad water in various disordered conditions of the stomach, liver, intestines, and kidneys, is well known. The powders, of course, are not only purgative in their action but are also decidedly antacid by reason of the important quantity of bicarbonate of sodium occurring in them.

CHLOROFORM PURISS. B.P. (PLANET BRAND).

(MAY AND BAKER, GARDEN WHARF, CHURCH-ROAD, BATTERSEA, LONDON, S.W.)

We have carefully submitted this chloroform to a number of tests and the results were entirely satisfactory and in accordance with the guarantee that it is absolutely pure chloroform. The specific gravity was 1500. The evaporation of 20 cubic centimetres gave absolutely no residue. The chloroform was also free from any trace of decomposition products, as, for example, chlorine or carbonyl chloride.

"HUMANISED" MILK.

(THE HYGIENIC DAIRY SOCIETY, 26 AND 27, BUSH-LANE, LONDON, E.C.)

This is milk of excellent quality containing, according to our analysis, a maximum amount of the various nourishing constituents. The milk was particularly rich in cream, the amount of fat being as high as 5·00 per cent. The milk is carefully sterilised and accordingly was found to be sweet and sound on opening the bottle. No preservatives were traced. The total solids amounted to 12·70 per cent. and the mineral matter to 0·70 per cent. These results exhibit the composition of rich cow's milk which will bear dilution to approximate to the composition of human milk.

MALT EXTRACT BEER.

(THE STEVNS BREWERIES COMPANY, LIMITED, COPENHAGEN. LONDON: 1, WALBROOK, E.C.)

Analysis showed that this was a practically non-alcoholic beer containing a large proportion of malt extractives. The extractives amounted to no less than 22·75 per cent. In fact, the beer presented the composition of a rich malt extract. There can be little doubt, therefore, of its nourishing qualities. The alcohol by volume amounted to less than 1 per cent. The flavour was rich and malty.

VIRGINIA ETNA LITHIA WATER.

(THE VIRGINIA ETNA LITHIA SPRINGS COMPANY, 60, ST. MARY AXE, LONDON, E.C.)

Our analysis of this water agrees practically with that published in a pamphlet submitted to us. We found that the total mineral salts amounted to 42 grains per gallon, the principal ingredients being calcium sulphate, sodium sulphate, magnesium carbonate, and calcium carbonate. The quantity of lithia present is small and does not exceed four grains (calculated as bicarbonate) per gallon. Its shown presence was by the spectroscope after separating the lime salts. The water is regarded as valuable in the treatment of gout and rheumatism and urinary disorders. It shows an excellent condition of organic purity.

BORDEAUX NECTAR.

(PETER R. MCQUIE AND SON, 19, SOUTH JOHN-STREET, LIVERPOOL.)

The features of this excellent grape juice are a freedom from alcohol and the absence of preservatives. It has a pleasant acidulous taste and forms an excellent beverage diluted with aerated water. Analysis gave the following results: total extractives, 16·20 per cent.; mineral matter, 0·30 per cent.; sugar, 14·70 per cent.; and tartaric acid, 0·645 per cent. The juice thus contains practically the entire constituents of the grape.

IOLA FOOD.

(C. MELIS AND CO., 37, CRUTCHED FRIARS, LONDON, E.C.)

Iola food occurs in the form of a jelly with a pleasant fruity flavour. Our analysis shows that it must be regarded as having distinct nourishing qualities since it contains not only an easily digested sugar but 10 per cent. also of protein as well as 1·76 per cent. of mineral salts rich in phosphates. It is practically soluble in water and is a very palatable and easily assimilated food free from acid, starch, and fat. The food in fact shows an alkaline reaction to litmus paper.

OATMEAL STOUT.

(MATTHEW BROWN AND CO., LIMITED, POLE-STREET, PRESTON.)

The analysis of this stout was as follows: alcohol by volume, 5·78 per cent.; extractives, 4·70 per cent.; mineral matter, 0·45 per cent.; and protein, 0·41 per cent. Though the amount of malt extract is relatively small, yet this contains about 10 per cent. of protein, while the mineral matter is rich in phosphate. These respective dietetic gains are due, no doubt, to the use of a proportion of oatmeal in the brewing process. The stout was in sound condition and possessed the delicate bitter flavour of genuine hop and also that of malt.

GLAXO.

(JOSEPH NATHAN AND CO., LIMITED, 88, GRACECHURCH-STREET, LONDON, E.C.)

Glaxo presents according to our analysis exactly the same food elements as does cow's milk, leaving out of account the water, but the constituents have been modified with the view of increasing their digestibility. The results were as follows: fat, 30·90 per cent.; proteins, 24·16 per cent.; milk sugar, 36·64 per cent.; mineral matter, 5·00 per cent.; and moisture, 3·30 per cent. The amount of fat present, as it is said, in the form of fatty acid is remarkable. It represents the maximum found in cow's milk of good average quality. The powder was soluble in water but some of the fat separated in a form resembling butter and rose to the top. It is seldom that dry preparations intended for the feeding of infants and invalids are found to contain such a large proportion of fat. The many dietetic purposes to which glaxo may usefully be put are obvious and we can well believe the statements that have reached us in regard to the satisfactory results which its administration for the purposes of a food has secured.

SACRATINTA (SACRAMENTAL WINE).

(H. STODDART AND CO., 20, SUFFOLK-STREET, PALL MALL, LONDON, S.W.)

The analysis of this wine was as follows: alcohol, by volume, 13·43 per cent.; extractives, 24·72 per cent.; and mineral matter, 0·57 per cent. The extractives consisted chiefly of sugar, and having regard to the amount it may be judged that the wine is very sweet to the taste. We do not doubt that it is a pure grape wine and the amount of alcohol indicates that it is of natural strength and unfortified.

CELLULON BREAD (DIABETIC).

(CALLARD AND CO., 74, REGENT-STREET, LONDON, W.)

We have not examined a specimen of bread (practically free, as this is, from starch) with a more satisfactory flavour. It is difficult to believe, judging from its taste, that the bread is not made from fine whole wheat meal, and yet the starch, and, indeed, the total carbohydrates, according to our analysis, are less than 3·0 per cent. It is particularly palatable when eaten with butter. The bread was quite attractively moist and kept so for some time. The protein amounted to 22·93 per cent. and the fat to 9·30 per cent. The bread is obviously suitable for the diet of the diabetic and others to whom foods rich in carbohydrates are undesirable.

first place the railway stations which were used by the pilgrims were liberally supplied with latrine accommodation and filtered drinking water and along the main roads leading to the Khaligat temple filtered water posts were erected every 100 yards and many latrines connected with the adjacent sewers were also constructed. The courtyard of the temple was properly drained and lighted and filtered water was supplied to it. The public hotels and the private lodging-houses for pilgrims were all placed under sanitary inspection and a large extra staff of sanitary workers of various grades was employed, including two special food inspectors who had power to destroy all unwholesome food which they could find. To prevent the outbreak of water-borne disease the use of foul water in the tanks round the temple was prohibited and these were guarded by the police; the water in them was treated with iron sulphate as some precaution in the event of their being used in spite of the order, and one large tank was cleared by running water. Pilgrims were warned by posters and "beat of drum" of the danger incurred by drinking the water of the Tolly's Nullah stream, which is always crowded with country boats on these occasions. Adequate provision was also made for the sickness that must inevitably occur in so huge a concourse as was expected. A dispensary was erected for minor ailments and special hospital accommodation was provided, chiefly with a view to the reception of cases of cholera which were the great dread of those in charge of the sanitary arrangements. Three hospitals with about 400 available beds were prepared for these cases and an ambulance service in connexion with them was provided, in addition to which special provision was made at the Shanagore Burning Ghat for the disposal of the dead. All of these sanitary and medical arrangements were under the charge of Dr. Mullan, health officer of District IV.; the members of the large staff under his control wore distinctive badges according to their grade. We are indebted to Dr. T. F. Pearse, health officer of Calcutta, for this account of the arrangements and we are glad to think that this thorough and well-planned organisation saved the city from such disastrous effects as have in the past followed on vast religious festival gatherings in our Eastern Empire.

THE LIME AND THE LEMON.

THE lemon is a deservedly popular fruit and serves as the foundation of that excellent beverage known as a lemon squash which, perhaps, is the best example of an absolutely non-alcoholic drink. The lime is not so well known, although from the point of view of flavour it is regarded by many as being even superior to the lemon. In view of the fact that there is now a good and abundant supply of limes to this country it is interesting to contrast the analysis of this fruit with that of the lemon. According to an analysis which we have recently made it would appear that the lime, although smaller than the lemon, yields weight for weight a good deal more juice. Thus the average amount of juice expressed from a lemon was 37·50 per cent. of its weight, whereas the lime gave 59·00 per cent. Moreover, the lime gives more citric acid but less sugar, as the following analyses show:—

	The juice of the lemon.		The juice of the lime.	
Total solid matters	8·80	per cent.	... 8·64	per cent.
Sugar	2·30	"	... 0·70	"
Citric acid	4·57	"	... 5·60	"
Mineral matter	0·36	"	... 0·35	"
Potash	0·15	"	... 0·12	"
Phosphoric acid (soluble) ...	0·010	"	... 0·066	"

The lime therefore yields a "drier" juice and contains a third of the quantity of sugar present in the lemon. The antiscorbutic properties of lime juice may be regarded as more marked than those possessed by the juice of the lemon. While the alkaline salts amount to practically the same in both fruits yet the phosphoric acid is greater in the lime than in the lemon. It is probably owing to the richness in alkaline salts that the use of lemon juice, as well as other fruit juices, is helpful in some diseases of the skin and in preventing eczema. The juice of the lime is equally valuable in this respect if, indeed, in regard to some dietetic points it is not superior. To those who are asked "to think imperially" there is another point about the lime which may appeal to them: it comes from British colonies and not from foreign countries. Fiscal reasons apart, the lime is an excellent and wholesome fruit and it seems a pity that we do not hear as frequently of a "lime squash" as we do of a "lemon squash."

LUNACY IN NEW ZEALAND.

IN his report on the events of the year 1906 Dr. J. F. S. Hay, Inspector-General of Mental Hospitals in New Zealand, states that the number of registered insane persons on Dec. 31st in that year was 3206, including 34 Maoris, of whom 1900 were males and 1308 were females. There are eight mental hospitals in the colony, the largest being the one at Dunedin (Seacliff), with 754 patients. Excluding the Maori race, the population of the colony is 888,578, of whom 606,247 are native-born and 282,331 are persons who have gone to the colony from all parts of the world, while the total number of the insane is 3172, of whom 988 are, and 2184 are not, native-born. It will therefore be seen that the native-born constitute more than two-thirds of the population, but furnish less than one-third of the insane. To put it otherwise, though there is one person insane in 280·4 of the total population, among those born in New Zealand there is only 1 in 613·6 and among persons who were born outside the colony 1 in 129·2. Only 34 Maoris were registered as insane; there is no available information as to the incidence of insanity among this section of the population.

CASE OF ANTRAL SUPPURATION PRESENTING UNUSUAL FEATURES.

IN the first issue of the *Royal Dental Hospital Gazette* an interesting case of antral suppuration, in which the symptoms were obscure, is recorded by Mr. J. G. Turner. The patient was a female, aged about 55 years, very neurotic, who complained of severe neuralgic pains of the left side of her face and head of many years' standing—probably 20 at least. Her peculiar mental condition made it impossible to get a history or to trace any coherence in the distribution or occurrence of her pain. One point only stood out—that she always began her tale of woe by reference to the left maxilla. The mouth was edentulous and all that called for note was a slight fulness of the left maxillary tuberosity as compared with the right. There was no tenderness observable. Examination of the nose and antral transillumination were negative; a radiograph showed no sign of teeth. No treatment improved her and eventually it was decided to explore the left tuberosity—influenced by the slight fulness and the persistent reference of pain to that part. On opening into the tuberosity, the crown of a molar tooth was met with and its extraction was followed by a gush of mucopus from the antrum. The roots of the tooth were almost absorbed and the remains of the periodontal membrane were engorged showing that the surrounding bone was inflamed. The patient was greatly relieved but did not make marked improvement until the lapse of three months. The case is of interest on account of the almost entire absence of tangible signs and because the patient's neurotic condition nearly led to a *diagnosis* of hysteria. Her nose and antrum were examined with negative results and it was practical schools for teaching all technical matters connected with meat-supply. Then, and then only, will it be *possible fully to comply with the requirements of the Local* Government Board that animals should always be killed by properly trained and licensed slaughterers.

The London County Council and the Inebriates Act of 1898.

Is the State solely responsible for the control and maintenance of criminals, lunatics, and other classes of defective persons who need segregation in the interests of the community, or should local authorities be expected to undertake or to share this unpleasant duty? This ancient question, which has been settled, probably for all time in this country, so far as criminals are concerned, remains open when the other classes fall to be dealt with. The growing opinion of all thoughtful people has certainly been that in respect of inebriates the State and the local authorities should share the burden, and this view found expression in the Inebriates Act of 1898. This Act was passed to facilitate the better treatment and control of habitual drunkards. The desirability of such a measure, to render unnecessary the repeated imprisonment of drunkards, had been obvious for some years previously and it was welcomed by all who took an intelligent interest in the welfare of this unfortunate class. Certain institutions were called into existence known as reformatories for inebriates, to which judges and magistrates could send persons who became qualified for committal by reason of drink-caused crime or persistent public drunkenness and disorder. The State was authorised to provide accommodation for criminal inebriates sent from higher courts and local authorities or private persons were permitted to establish institutions for the reception of drunk and disorderly persons committed from petty sessional courts. The State was given power to pay the whole cost of the former class and to share with local authorities the maintenance of the latter. No difficulty has been experienced in working the Act so far as it relates to criminal inebriates maintained entirely by the State, but considerable difficulty has been experienced in inducing local authorities to accept any responsibility in regard to those other cases committed under the section (Section 2) which allowed of combination for maintenance cost, where necessary, between county or borough councils and the State.

When the Act became law the Government decided to facilitate the establishment of institutions by agreeing to pay a fixed capitation grant of money for every inebriate person committed from a petty sessions under Section 2 of the Act, provided that the local authority having jurisdiction over the area within which the court was situated also agreed to contribute towards the maintenance of every person *so* committed. Having at the time no actual experiences but only estimates as a guide the Secretary of State found it impossible to calculate the exact amount which would be necessary for the proper maintenance of inmates; but a sum of 10*s*. 6*d*. per head per week was decided upon as an experimental amount to be given to managers of reformatories by the Treasury, provided that local authorities also contributed 7*s*. per head from local funds, making 17*s*. 6*d*. in all. The Government contribution of 10*s*. 6*d*., although only guaranteed for three years, was continued without change for seven years. At the end of seven years experience warranted a reduction in the Government grant. The accounts of seven out of eight institutions in full working order during 1906 showed that cases were being detained at a cost varying from 10*s*. 4*d*. to 14*s*. per inmate per week; but, the eighth, "Farmfield" (managed by the London County Council) was not conducted at less than a weekly rate of 18*s*. 6*d*. per head. It was felt that 14*s*. per week should be considered the total amount necessary for maintenance and that the managers of all reformatories should be induced to bring down their expenses to that sum per head. Moreover, in furtherance of the view that the segregation of inebriates relieved imperial and local funds about equally it was decided that the Government contribution should be reduced from 10*s*. 6*d*. to 7*s*. to correspond with the 7*s*. provided by local authorities. This reduction, which marked in the simplest and most obvious way the joint responsibilities of the State and the local authorities, was accepted as reasonable by the managers of reformatories, except, unfortunately, in the case of the London County Council, and the fear is lest the exceptional attitude of the London County Council should, by example, operate to the detriment of a valuable piece of legislation. At an early date after the passing of the Inebriates Act of 1898 the London County Council established a reformatory at Farmfield, near Horley, for the reception of 100 female inebriates. It soon became evident that more accommodation would be necessary and the Council accordingly contracted with the National Institutions for Inebriates for the reception of all cases unable to be received at Farmfield, agreeing to pay 7*s*. per head per week for each case. Under this arrangement, at the end of last year, about 600 London inebriate women were under reformatory care, 100 at Farmfield and 500 in the reformatories managed by the National Institutions for Inebriates. But in May last the Council gave notice to terminate its agreement with the National Institutions in the following December unless the Government grant of 10*s*. 6*d*. were reverted to for all cases committed under Section 2 of the Act. As such action by the Government would have supplied an unnecessary amount of money to the managers of institutions who did not need, or ask for, any increase and would have entailed a large increase of unjustifiable public expenditure, the offer of the Council was declined and the contract between the Council and the National Institutions for Inebriates accordingly ceased on Dec. 31st, 1907. A few vacancies amongst the 100 beds at Farmfield will probably be available from time to time, but these will be so few as practically to render the Inebriates Act useless so far as London is *concerned*, which means that at least 500 women now under the only sort of care which can save them from themselves and protect the community from the results of their weakness will be thrown back upon the streets, police courts, and prisons without hope of reform.

In short, the step now taken by the Council will involve reversion to the discredited system of treating inebriates (many of whom are diseased, epileptic, and mentally

Union Society, which was constituted a year ago "to hold debates and to promote social intercourse amongst students and members of the University." Its officers, who have worked hard to give it a successful start, have, we are informed, modelled it on the lines of the unions existing at Oxford and Cambridge, and in this work they have received the sympathetic support of their Convocation. The secretary has also visited Lille to observe the arrangement and details of the building which is devoted to the Students' Union of that University, for it is hoped that the London society will soon have a house of its own. Meanwhile half a dozen debates have been held by the hospitality of various constituent colleges, but we note that only one member of the medical faculty, a lady, has represented the rhetorical force that lies latent in it; in fact, speaking generally, the medical faculty is poorly represented. A little argument on political or social problems is an excellent corrective for a surfeit of "shop," and young men will find the training of declaring their convictions before a not too lenient audience an admirable one in many ways. All members and recognised teachers of the University are eligible for membership on an annual payment of 5*s*., and regular students of any school of the University can be made associate members at the discretion of the committee. It is intended to invite distinguished persons to open debates from time to time. We shall watch the career of the union with interest.

CONDITION OF THE EYES IN MEN OVER 60 YEARS OF AGE.

A VALUABLE statistical inquiry into the refraction and some pathological conditions of the eyes of 500 men above 60 years of age has been recently conducted by Dr. D. W. Greene of Dayton, Ohio, and has been published in the January number of *Ophthalmology*. The subjects of the examination were inmates of the National Military Home near Dayton who had been drawn from the middle and lower labouring classes. Blood pressure was taken with the Janeway sphygmomanometer and 130 mm. Hg was taken as the normal standard, but 112 men gave a reading of 145 mm. Hg and under, and 438 above that pressure. Dr. Greene found that arterio-sclerosis was of frequent occurrence. As to the nationality of the 500 men it was found that 328 were Americans, 59 were Germans, 85 were Irish, 12 were English, and 6 were not recorded; one was a Swiss, one a Swede, one an Austrian, two were French, four were Canadians, and one was a Welshman. 290 men presented cataract in some stage of development and of these 187 were Americans, 35 were Germans, and 52 were Irish; a few escaped registration in regard to their nationality. The average age of the 500 men was 70·76 years. In regard to occupation, 371 had followed hard and laborious callings, such as farmers and day labourers, and of these the majority had a blood pressure of from 160 to 280 mm. Hg; 142 had followed less laborious callings, such as those of clerk and bookkeeper, and in these the blood pressure was as a rule much lower. Drinking habits were inquired into in nearly every case; 89 claimed to be temperate, 86 were regular drinkers, 45 drank periodically, 240 claimed to be moderate drinkers, and the habits of a few were not noted. The examination of the blood pressure charts showed that the influence of alcoholic drinks in the causation of arterial disease has probably been over-estimated, and that as an etiological factor it does not compare with tobacco when used to excess. In regard to specific history 34 men admitted the disease and 420 denied it; no record was obtained in 26. In the majority of those who had had syphilis the blood pressure was above the normal, some considerably above it. Of 910 eyes, not men, conforming to the requirements of the examination 529 had some kind or degree of lens opacity. Of some of these he had no satisfactory record, so that the ratios are on a basis of 504 eyes. Of these 50 were classed as mature cataracts, 102 as incipient cortico-nuclear, 255 as incipient cortical; 84 as incipient nuclear, seven as post-polar, four as capsular, and two as traumatic. The eyes with incipient cortical cataract had an average age of 69·4 years, ranging from 60 to 95. The blood pressure in 5·9 per cent. was below the normal, the average being 117·7 mm. Hg. In 31·8 per cent. the blood pressure was between 130 and 160 mm. Hg, and the average age was 67·8 years. In 62·3 per cent. the blood pressure was over 160, the average being 177.5 mm. Hg. Similar observations which must have taken up much time and demanded much attention and care are given for each of the other forms of opacity of the lens. In regard to the colour of the irides 3 per cent. had black eyes, 34·6 per cent. had blue eyes, 30·1 per cent. grey eyes, 19·2 per cent. hazel eyes, and 13 per cent. brown eyes. The average pupillary distance was found to be 6·2 centimetres (about $2\frac{7}{16}$ inches). The transverse diameter of the cornea was 12 millimetres. The average size of the pupil was 3·3 millimetres. Two or three drops of a 1 per cent. solution of homatropine usually doubled the diameter of the pupil in men between 60 and 70 years, but after 70 the pinhead pupil so often seen will not generally enlarge quite so freely. No case of glaucoma resulted from the use of the mydriatic.

THE UNITED KINGDOM HOSPITALS CONFERENCE.

THIS conference will be held on Wednesday and Thursday next, April 1st and 2nd, at University College, Gower-street, London, W.C. The first session will take place on Wednesday afternoon at 2 P.M., when after the appointment of a chairman and other formal business the members of the conference will discuss the questions of payments to the hospitals by hospital patients; of the prevention of hospital abuse by the employment of almoners and by the coöperation of provident dispensaries and similar institutions with hospitals; and the methods of election of the honorary hospital staffs. The Hon. Sydney Holland, chairman of the London Hospital, Colonel Montefiore of the Charity Organisation Society, and Mr. H. A. Harben, treasurer of St. Mary's Hospital, will speak to motions on these subjects if hospital representatives show a desire to raise specific points. On Thursday the conference will meet for its morning session at 10.30 A.M. when the subjects set down for discussion are the organisation of county guilds for assistance in hospital work, and the desirability of a uniform method of keeping hospital accounts. At the afternoon session the subjects set down are the advisability of the notification of pulmonary tuberculosis and the provision of isolation hospitals for such cases; the desirability of medical men having more voice in nominating representatives for election to hospital boards of management; and the question of provision of temporary accommodation in hospitals for mental cases. This is the third conference and it is hoped that they will be annual events.

PULMONARY EMBOLISM FOLLOWING AN OPERATION.

IN the *Boston Medical and Surgical Journal* of Feb. 27th Dr. C. G. Cumston has reported a case of a rare but disastrous sequel of operation—pulmonary embolism. A single woman, aged 29 years, came under observation. Menstruation had been regular until the age of 23 years, when the amount of blood lost began to increase and she complained of pain in the back and left side. At the age of 27 years menstruation became irregular, occurring at intervals of three, five, or six weeks. She was strong and well developed. In the left side of the abdomen was a at the term "infectious" is too loose a term to apply both measles and tuberculosis, suggesting the term sub-infections" for the latter, would seem to be one hich adequately expresses the present state of opinion on e matter. *Assuming for the moment that case to case* nfection is an established fact it is of some interest to onsider the *results of experiments in regard to the infective* haracter of the sputum of tuberculous patients devised with he object of determining the manner in which air-borne nfection takes place. Here, again, there is no unanimity of pinion and Dr. BULSTRODE in his *report gives a* useful *résumé* of the contentions of the two conflicting schools of pinion—viz., the theory of dust-borne infection by dried bacilli, resting upon the experiments of KOCH, CORNET, and others, and that of droplet infection through coughing, of which FLÜGGE is the chief exponent. The experiments in regard to dried sputum are so well known and have exerted such an influence in regard to the manner of *dealing with* sputum that no special reference to them is necessary; those of FLÜGGE and his followers, on the other hand, have not at the present time obtained the notice which they *deserve. The presence of* bacilli in the fine impalpable droplets of saliva or sputum sprayed *from the patient* during the expiratory efforts of sneezing, coughing, and loud speaking has been definitely shown, and experiments further demonstrate that these droplets may be widely disseminated, even to *some considerable* distance *from* the patient. FLÜGGE and his followers believe that the *danger* of infection from such droplets is much greater than that from dried bacilli in dust. Numerous observers, notably RANSOME and DELÉPINE in this country and CADÉAC in France, have maintained that *the* tubercle bacillus rapidly loses its virulence in daylight and if *exposed to* air, while on the other hand CADÉAC confirms the danger of bacilli in the moist state in droplets. The practical inference to be drawn from such experiments is that the consumptive person *should be taught* to cough into the sputum flask as well as to spit into it, or that he should hold his handkerchief before the mouth during coughing or sneezing—a precaution which is *now* taught in many sanatoriums but is by *no means* generally adopted by the sufferers *from* pulmonary tuberculosis *or* even *taught* by those who have charge of them. It is obvious that the *factors* which lead to infection with the tubercle bacillus *are, as* in *all* other infections, those of exposure to infection and of defective *resisting* power. Pathological observations seem to show that at some time in their lives the majority of people become the host of the tubercle bacillus by some channel *or* other. The problem is therefore complicated *in any* given case by the possibility of auto-infection from a lesion long quiescent. *There is* a danger that the uncertainty which exists in regard to personal infection, and the growing importance which is *being attached to* conditions of general and personal hygiene, may lead to a lessening *of* precautions in regard to the bacterial factor in the *disease*, which would be a condition *most* deeply to be deplored. While uncertainty exists *in* regard to the spread of such a widespread disease the *most rigid* precautions should be carried out, the more so that these precautions are only those which cleanliness and decency dictate. If therefore the *consumptive* observes such precautions it is a hardship to treat him as if he were a dangerous person. On the other hand, we welcome *the efforts which are now* being made to deal with the matter of the personal factor of susceptibility by endeavouring *to improve the conditions* under which the population generally live and work.

Annotations.

"Ne quid nimis."

THE SUPPLY OF PURE MILK.

Dr. J. Niven has made an important contribution to *the local* press of Manchester *on the* best way of insuring a supply of pure milk. *He says* that the report of the Royal Commission on Tuberculosis has added to the evidence that "tuberculous milk powerfully reinforces the store of human tuberculosis." *To check human tuberculosis and to render* the dairying industry of the country more prosperous he says that the dairy farms must be provided with a sufficiency of well-constructed, well-lighted, and well-ventilated cowsheds of a prescribed cubic *capacity per cow, and tuberculosis must be eradicated* from the herds. We know that badly built, dark, and dirty buildings which cannot be readily or completely cleansed or disinfected *are in many parts of the country* the rule rather than the exception. Here the presence of one cow, so affected as to part with tuberculous matter, might infect the others without it being possible to remove the infection from among them. Unless such premises *could* be thoroughly disinfected it would be of no use to substitute a *fresh herd free from the* disease and to expose them to the danger of being infected. Something, however, has been done in Manchester since 1896 to reduce the quantity of tuberculous milk taken into the city. The cowsheds of the city have been largely reconstructed. The Manchester Pure Milk-Supply Company has effected much good. In 1899 the Manchester milk clauses were obtained and by the way in which they have been carried out the *amount* of tuberculous milk going into the city has been reduced more than one half, the mortality from tuberculous diseases has fallen considerably and the stock kept in dairies supplying Manchester has much improved. Professor S. Delépine bears witness that the general disease-*producing* power of the milk *going into the city* has been greatly reduced and that the degree of cleanliness is much higher. But, as Dr. Niven remarks, all these means "are not calculated to lead to the entire suppression of tuberculous milk." There seem to be two courses open: "One is to schedule open, or clinical, tuberculosis as a contagious disease and to remove from the herds plainly tuberculous animals. The other is to eradicate tuberculosis from dairy herds." This would involve the creation of a veterinary public health service. Their duty should be to determine what farms are at present fitted to have their stock rendered non-tuberculous and *to* take the necessary action. Such farms, few at first, would gradually increase and might be used for raising non-tuberculous stock. Dr. Niven goes on with an ingenious scheme, dealing with millions sterling, the elaboration of which must have been a *joy to* a mathematical mind, which scheme would in about 15 years have well repaid the cost to the country in the economy of life and the *increased prosperity of the dairying* industry. But if tuberculosis is eradicated from our dairy cows there still remain the dangers of contamination between the cow and the *consumer. Scarlet* fever and enteric fever are easily carried and it may prove *almost more* difficult to guard against such dangers than to eradicate tuberculosis.

durable than one obtained by any other system of treatment. It is advisable that the patient should always wear a knitted stocking bandage (*Trikot-Schlauchbinde*). At the same meeting of the society a second paper on this method of treating ulcers was read by Dr. Faullimmel of the district hospital at Bischweiler. He said that he had many cases of ulcer of the leg under his care, and after trying a variety of methods of treatment he had found Professor Unna's to be by far the most successful, economical, and convenient.

THE FORMATION OF LACTIC ACID AND CARBONIC ACID DURING MUSCULAR CONTRACTION AND RIGOR MORTIS.

THE *Cambridge University Reporter* of March 17th contains an interesting communication from Dr. P. W. Latham on the above subject. He points out that by combining prussic acid with pyruvic acid (acetyl formic acid formed by the dry distillation of tartaric acid) and subsequent hydrolysis methyl-tartronic acid is produced. This acid on decomposition resolves exactly into lactic acid and carbonic acid. Dr. Latham suggests that the nitrile of methyl-tartronic acid which by hydrolysis is resolved into carbonic acid and ammonia formed one of the constituents of proteid matter and that during muscular contraction the ammonia group combined with other constituents, the lactic acid and carbonic acid being alone set free. Some support is given to this view from the fact that in the earlier stages in the genesis of organic matter in plants the nitrile of methyl-tartronic acid can be formed from acetic anhydride and prussic acid. Schutzenberger in his experiments on the decomposition of albumin obtained among other products an isomeride of aspartic acid which differed from it, however, by being highly soluble in water. The suggestion now is that this body was iso-aspartic acid originating from the nitrile of methyl-tartronic acid. Another substance obtained by Schutzenberger was probably a compound of glycocoll and iso-aspartic acid. The conclusion is that these two substances being derived respectively from amino-malonic nitrile and methyl-tartronic nitrile may be regarded as constituents of the living protein molecule.

INFANTILE MORTALITY AT GRIMSBY.

Dr. W. B. Simpson, the medical officer of health of Grimsby, has prepared a careful report for the instruction of his fellow townsmen upon the subject of infantile mortality, wherein he lays stress upon the municipal responsibility for checking the wastage of human life. The total death-rate of infants under 12 months is still as high as 176 per 1000, and the report suggests certain conclusions, having regard to the admitted facts that a high infantile mortality is a feature common to the majority of our large provincial towns, and that those towns having a large proportion of women working in factories are prone to suffer most severely. Dr. Simpson considers that infantile mortality in the borough of Grimsby is excessively, if not abnormally, high, and alludes to the fact that the total of infantile mortality in Grimsby is largely augmented by the excessive prevalence of diarrhœal diseases. He goes on to point out that diarrhœa is a "filth" disease, is infective, and is associated with decomposing organic material, adding that its incidence coincides with the "swarmi [illegible] housefly, and [illegible] ticles and
houseflies r [illegible] carriers [illegible] aterial.
He conside [illegible] m of d [illegible] emental
material in [illegible] efectiv [illegible] to the
ready conv [illegible] ve ma [illegible] d of
infants, and [illegible] wing [illegible] this
unfortunate [illegible] op
of Births A [illegible] t
visitor; the [illegible] the establishment of a model crèche school; the replacement of all box privies by water closets; and more frequent removal of all refuse from the vicinity of dwellings, especially during the autumn months, urging that accumulations of decomposing organic refuse in the vicinity of dwellings are at all times a menace to health, and especially so in the case of infants. We thoroughly believe in the efficacy of taking the public into the confidence of the medical officer in dealing with such matters as infantile mortality, and Dr. Simpson may rely on receiving general support for his views. We think it would have been well, however, if he had not pressed the virtues of the Notification of Births Act without allusion to its obvious unfairness to the medical profession.

AT a quarterly meeting of the board of management of St. Mary's Hospital held on March 19th the following motion was moved from the chair and carried unanimously:—

> That the best thanks of this board be given to Dr. Robert Henry Scanes Spicer for the valuable service he has rendered to the hospital for the past 20 years as surgeon for diseases of the throat and that he be, and is hereby elected, honorary consulting surgeon for diseases of the throat.

THE Department of Public Health of Queensland in a bulletin dated Feb. 15th states that no case of plague has been notified at Brisbane during the week ending on that date. The last case notified occurred on Feb. 7th. During the week ending March 21st the Acting Governor of the Gold Coast has reported five deaths from plague at Accra, two at Cape Coast, and three near Oblogo. All other localities are free from plague.

A VERY successful meeting of the Medico-Legal Society was held on Tuesday last, March 24th, when Mr. R. Henslowe Wellington continued the adjourned debate upon Death under Anæsthetics in a paper raising the question of the legal liability of the anæsthetist in case of catastrophe. An interesting debate followed and over 80 members were present.

THE death of Dr. Robert Barnes, which was followed at so short an interval by the death of his son, Dr. R. S. Fancourt Barnes, left vacant two posts as consulting physicians to the Royal Maternity Charity of London. Dr. Henry Gervis and Dr. George Ernest Herman have been unanimously elected by the committee to fill the vacant posts.

Dr. Philip Crampton Walker of Pretoria and formerly of Liverpool has since Feb. 10th been discharging the duties of medical officer of health of the Transvaal Colony in place of Dr. George Turner who has retired, and Dr. Walker will continue to do so until further official notice.

Looking Back.

FROM

THE LANCET, *SATURDAY*, March 27th, 1830.

MEDICAL INSPECTION.

WE understand that a medical inspection is now in pr[illegible]gress at all the depôt stations throughout England, for th[illegible] purpose of ascertaining the actual efficiency of the men, a[illegible] in order that such may be discharged, particularly those [illegible] limited services, who shall be reported to be, either from o[illegible] age or disability, unfit for active duty. The stations nort[illegible] of London, as far as Fort George in Scotland, have be[illegible] [illegible]sted to Staff-Surgeon Henry Marshall, accompanied b[illegible] [illegible]l M'Grigor; those to the south of London, to Sta[illegible] Sir Andrew Halliday, M.D.

persons in charge of the organ or not they come under the second section of the Cruelty to Children Act, 1904, which enacts that "If any person causes or procures any child, being a boy under the age of 14 years or being a girl under the age of 16 years, or having the custody, charge, or care of any such child, allows that child to be in any street, premises, or place for the purpose of begging or receiving alms or of inducing the giving of alms, whether under the pretence of singing, playing, performing, offering anything for sale, or otherwise, that person shall on summary conviction be liable at the discretion of the court to a fine not exceeding £25, or alternatively, or in default of payment, or in addition thereto to imprisonment with or without hard labour for any term not exceeding three months." The same section imposes similar penalties upon those responsible for children of the ages above mentioned singing or performing on licensed premises between 9 P.M. and 6 A.M., or at any time of the day when the child is under 11 years of age. It is likewise an offence to expose a child under 16 years of age to pain or to the risk of bodily injury by allowing him or her to be in any place for the purpose of being trained as an acrobat, contortionist, or circus performer, or of being trained for any exhibition or performance which in its nature is dangerous. Exceptions are permitted in order to prevent hardship in cases where no harm to the child is likely to result, and it cannot be said that children are not protected, so far as the law is concerned, from forms of ill-usage likely to be prejudicial to their physical and moral health.

THE TREATMENT OF PULMONARY TUBERCULOSIS.

WE have received a pamphlet entitled "Summary of Report on the New Remedies for Tuberculosis Prepared by Dr. Toru Ishigami, Director of the Ishigami Institute for Infectious Diseases and Sanatorium for Tuberculosis, Hamadera, Osaka." After prolonged investigation Dr. Ishigami has succeeded in obtaining two products for the treatment of tuberculosis which, he maintains, are of great efficacy and without any detrimental "side action." The one is a chemical preparation from tubercle bacilli and is applicable to patients without fever and the other is an immunisation serum and is suitable for patients in an advanced stage of the disease. The chemical product he has named "tuberculo-toxoidin." It is obtained by dissolving the culture of tubercle bacilli in pure sulphuric acid in order to destroy the toxicity and by a further series of processes the remedy is finally obtained in the form of a weak alkaline solution. This substance can be injected subcutaneously without producing any local irritation and may be given in comparatively large doses without injurious effects. Dr. Ishigami gives statistics of the cases which he has treated, and out of 160 patients, 69, or 43·13 per cent., are reported as being completely cured. 219 patients were treated in the same manner by other physicians, and 36·1 per cent. were stated to have been cured, and another 36·1 per cent. were "partially cured." With regard to the immunisation serum, Dr. Ishigami commenced his investigations in 1897. At first he found it difficult to obtain a strong serum free from the characteristic reaction of animal serum so detrimental to tuberculous patients. He finally succeeded in obviating this reaction and in making a thoroughly efficient immunisation serum by injecting his tuberculo-toxoidin. An account is given of the action of the serum in cases of acute tuberculous meningitis, of tuberculous peritonitis, and of painful tuberculous arthritis. The results were encouraging. In cases of pulmonary tuberculosis with high fever or with disordered nutrition, and when the patient is unfit for the tuberculo-toxoidin treatment, the serum injection may be first resorted to until the symptoms become alleviated and the fever disappears and nutrition is improved, when the tuberculo-toxoidin can be employed. 169 patients were treated in this manner, of whom 22·7 per cent. were "completely cured" and 33·33 per cent. "partially cured." Dr. Ishigami has ascertained that the internal administration of the tuberculo-toxoidin and of the immunisation serum is harmless and efficacious. He indicates the classes of cases suitable for this method of treatment. We are informed that a supply of tuberculo-toxoidin will be supplied gratis to any hospital or medical practitioner on application to Mr. R. Wilkinson, care of Messrs. Curtis and Co., Limited, 51, High Holborn, London, W.C.

AN INTERNATIONAL MEDICAL ASSOCIATION AGAINST WAR.

THE International Medical Association for the Suppression of War celebrated the fourth year of its existence by a reunion held on March 21st at the residence of Dr. J. A. Rivière, the founder and President. The association now numbers 3000 medical men of all nationalities. Dr. Rivière in his presidential address mentioned that it was hoped that the association would organise a great manifestation in the cause of peace at the forthcoming International Exhibition which it was intended to hold at Paris in 1911. Various motions dealing with the causes which the association has at heart were proposed and carried, among which were one congratulating Sir Edward Grey on his action regarding Macedonia and another congratulating the Chinese Government upon being willing to submit the difficulty with Japan to arbitration. While, unfortunately, it cannot be considered that the total abolition of war is within sight at present, yet the desire for such is widespread. No body of men knows better than the medical profession the horrors of war as a cause of disease not only among the fighting ranks but also among the inhabitants of the countries concerned, and it is therefore fitting that medical men should be leagued together to insure, if possible, the preservation of peace.

THE SANITARY SAFEGUARDING OF A GREAT RELIGIOUS FESTIVAL IN INDIA.

THE religions of the East are the cause of the gathering together at regular intervals of greater concourses of people than European cities are accustomed to accommodate, if we except the massing of armed forces, and these religious gatherings are occasioned by pilgrimages to some temple or sacred city from far and near. It is obvious that such pilgrimages are fraught with the gravest danger to the public health, for the devotees may come with the seeds of all sorts of infective disease developing in them and one case of cholera or plague breaking out in such a herded company is as a spark dropped into gunpowder. During the summer of last year we published a series of articles from the British Sanitary Commissioner with the Constantinople Board of Health dealing with the accommodation and arrangement of the nine lazarets, or quarantine and disinfecting stations, by means of which the Turkish Empire defends the confines of Europe against the importation of Asiatic epidemic disorders by pilgrims returning from the holy places of Islam. We have recently received an account of the sanitary precautions which were taken in Calcutta at the festival of "Ardhodaya Jog," which was celebrated at the beginning of this month, precautions which show that the Indian authorities are put to no less anxiety from the concourses of the pious than are the sanitarians of Constantinople. We have not yet received advices as to the success of the precautions recently taken in Calcutta, but it is of interest to record them, as they form a noteworthy piece of municipal sanitary organisation which is of good augury for the developing sanitary service of India. In the or a Pravaz syringe contain $\frac{1}{5000}$th (0·0002) of a cubic centimetre, which is the initial dose required.

We have felt ourselves compelled to discuss these proportions somewhat fully because experience shows that erroneous views are held regarding the preparation and dose of T.R., and especially regarding the quantity of solid substance contained in one cubic centimetre of this preparation. For instance, on p. 1218 of THE LANCET of Nov. 2nd, 1907, in a paper entitled "Studies in Connexion with Therapeutic Immunisation," Sir A. E. Wright says:—

> Owing to the fact that the quantum of dry tubercle powder in Koch's T.R. (tuberculin) was, owing to an unaccountable error on the makers' part, declared by them as 10 milligrammes in one cubic centimetre, when it was in reality, as they now inform me, only 2 milligrammes in one cubic centimetre, the dose here inoculated would in reality be only $\frac{1}{2500}$th milligramme. A similar correction would, be it noted, be applicable to the doses of tuberculin as stated in this paper and in all my previous publications.

The practical application of tuberculin T.R. in clinical work has produced excellent results, as has been unanimously declared by a variety of authorities. For the treatment of patients it was of very little consequence to know the real amount of dry substance which the preparation contains, provided that the selection of the dose, and above all things the increase of the dose, was rightly undertaken. There was certainly no mistake on the part of the manufacturers of the preparation. From the earliest beginning to the present day the preparation has always been supplied in the same degree of concentration and consequently possessed of the same degree of activity. We believe that in the present article we have cleared up all the doubts and errors which exist, and we hope that the preparation of dilutions of tuberculin T.R. will not in future present any difficulty.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of the President and general council of King Edward's Hospital Fund for London to receive the accounts and the report of the general council for the year 1907 was held at Marlborough House on March 20th, His Royal Highness the Prince of Wales, the President of the Fund, being in the chair.

The PRINCE of WALES moved the adoption of the balance sheet, which was presented by Lord Rothschild, the honorary treasurer of the Fund.

Lord STRATHCONA seconded and the motion was carried unanimously.

Sir SAVILE CROSSLEY then read the draft report of the Council for the year 1907 which stated that the total receipts for the year amounted to £484,069 10*s.* 9*d.* This sum was made up as follows: donations, £5656 2*s.* 5*d.*; contributions to capital, £517 14*s.*; special donation, £100,000; annual subscriptions, £25,412 4*s.* 10*d.*; contribution of the League of Mercy, £18,000; from the Lewis estate, £212,500; legacies, £69,472 12*s.* 3*d.*; interest from investments, £51,260 17*s.* 3*d.*; together with £1000 from the trustees of the London Parochial Charities and £250 from the trustees of the Bawden Fund. The amount distributed was £121,000, including the £1000 entrusted to the Fund for distribution among convalescent homes by the London Parochial Charities. In addition to this, amalgamation grants of £2750 became due during the year and were paid. Since the inauguration of the Fund the amount spent on administration had been £1 5*s.* 8*d.* per cent. of the total amount received. During the year the sum of £212,500 was received from the executors of the will of the late Mr. Samuel Lewis on account of the legacy of £250,000 left to the Fund. The legacies from the late Mr. Alfred Beit of £20,000, the late Mr. John Nicholas of £10,000, and the late Lord Grimthorpe of £5000 (less duty) announced in 1906 were received, while a sum of £15,000 was received on account of the residue of the estate of the late Lieutenant-General G. E. Baynes, and a further sum of £10,932 on account of the residue of the estate of the late Mr. G. H. Heigham. The Fund had also to acknowledge the munificent donation of £100,000 from Mr. Andrew Carnegie. The amounts received in donations and subscriptions, excluding Mr. Carnegie's gift, showed, as compared with 1906, an increase of £1165 4*s.* 5*d.* The Drapers' Company had generously increased their annual subscription from £1500 to £3000. The League of Mercy had contributed £18,000, being the same amount as in the previous year. During the nine years of its existence the League had furnished in all £97,000 to the Fund. Every eligible hospital which had applied for a grant had been inspected and reported upon. On July 26th, 1907, the Bill for the incorporation of the Fund became law, and on the same day a meeting of the President and General Council was held at which all the committees were reappointed, and the same powers as they previously exercised, in so far as these powers were not inconsistent with the Act, were delegated to them. The Council states that the Act has appeared to work satisfactorily in every way. In February, 1907, a committee, consisting of Sir Eyre Massey Shaw and Captain Wells, was appointed to inquire into the best means of assisting the various hospitals to secure a greater degree of protection against fire, and in July they issued a report containing suggestions which had been circulated to the hospitals. A committee, consisting of the Presidents of the Royal Colleges of Physicians and Surgeons, together with Sir William Church and Sir Cooper Perry, had been appointed to revise the form of report supplied to the visitors to hospitals and that committee had improved this form and brought it up to date. During the year the Royal National Orthopædic Hospital took over the patients and some of the members of the staff and governing body of the City Orthopædic Hospital, and this amalgamation was now complete. The efforts to amalgamate the five throat, nose, and ear hospitals still continued, but the difficulties of negotiating with so many bodies is necessarily great and it has not been found possible yet to arrive at any definite conclusion. In connexion with the proposed amalgamation between the North-West London Hospital and the Hampstead General Hospital the Fund had made an offer with a view to the first-named institution being converted into an outpatient department in connexion with the Hampstead General Hospital.

The PRINCE of WALES, in moving the adoption of the report, said:—My Lords and Gentlemen,—The draft report which has just been read shows that the Fund has had a busy year. ...... Since our council meeting in December, acting on the advice of the Executive Committee, and in accordance with the powers given under the Act, I have decided to appoint a committee to inquire into the system prevailing in the London voluntary hospitals regarding the admission of out-patients. It is to be hoped that the labour involved in the holding of such an inquiry may perhaps, to some extent, be lightened by the results of the work of the Royal Commission on the Poor Laws, the issue of whose report we look forward to with great interest. In so far as the Commission may deal with certain aspects of the question of medical relief we cannot fail to profit by a perusal of the evidence given before them, and of the conclusions at which they arrive. We shall, therefore, defer our inquiry until the Commission has reported. Another matter to be brought to your notice is a development of the scope of the operations of the Fund which I have approved upon the recommendation of the distribution committee. Hitherto the hospitals with which we have dealt have been those lying in the County of London, or within seven miles of Charing Cross. This limitation was wisely imposed when the Fund was instuted in 1897. But in the 11 years which have since elapsed London has grown rapidly and it is felt that the time has come when we should enlarge our area. The radius from Charing Cross has, therefore, been extended from seven to nine miles. We also propose this year to consider the claims of consumption sanatoria in the country which take a large proportion of their patients from London. It must be obvious that such institutions are better situated in the country than in London or even in the suburbs. ...... The total of last year's distribution exceeded the income from investments by £70,000. With the extended area an increased income from subscriptions and donations will be necessary, and I trust that the public will recognise this and continue to give us their substantial support. ...... I now move the adoption of the report.

The motion was seconded by the Lord Mayor (Sir JOHN BELL), supported by the Chairman of the London County Council (Mr. R. A. ROBINSON), and by Lord BESSBOROUGH, chairman of the Executive Committee, and carried unanimously.

The Bishop of SOUTHWARK moved, and Lord REVELSTOKE seconded, a vote of thanks to the Prince of Wales for presiding. The vote being carried by acclamation,

His Royal Highness said: My Lords and Gentlemen,—I only a strong belief in a "physical basis for pain" which prevented an error in diagnosis. The probable course of events would seem to have been a nasal catarrh spreading into the antrum, into which the roots of the third molar projected, forming among them undrainable pockets; tissue infection spreading to the bone and periodontal membrane; absorption of tooth tissue (as in pyorrhœa alveolaris) and chronic pulpitis. This last would account for the neuralgic pain and the osteitis would account for the after pain. The case would seem to illustrate the importance of noting the smallest sign.

A PENSION FOR MR. J. HALL-EDWARDS.

IT was announced in the House of Commons on Monday last that a Civil List pension had been granted to Mr. J. Hall-Edwards, the well-known worker in x rays, who, as we have already reported, has suffered terribly in the prosecution of his scientific researches. The official pension is £120 per annum but the pension fund is so very small that hardly any larger sum could be expected from this source. The local fund which is being raised for Mr. Hall-Edwards should therefore still be vigorously supported. The treasurer, Mr. F. Marsh, 95, Cornwall-street, Birmingham, will give every information and will acknowledge subscriptions.

THE BACTERIOLOGY OF NOMA.

THE pathology of noma has been studied within recent years by many observers but at the present time there is considerable difference of opinion on the subject. Dr. E. Hellesen of Christiania has published a paper in the *Jahrbuch für Kinderheilkunde* for March in which he discusses the views put forward by other observers and records his own exhaustive observations on a fatal case of the disease. The commonly received explanation of noma is that it is a non-specific gangrene associated with debilitating or exhausting conditions, while some authorities postulate some disturbance of the innervation of the parts affected as a predisposing cause. Within the last few years a considerable number of observations have been carried out with the object of discovering some pathogenic organism or organisms in this condition. As Dr. Hellesen points out, the difficulties in the way of such researches are very considerable owing to the fact that the gangrenous tissues offer a very favourable culture medium for the growth of many organisms which may reach them from the mouth or from the air. It is not surprising therefore that the results hitherto obtained have not been concordant. In 1890 Grawitz observed numerous bacilli in sections made from the necrotic tissues of a case of noma; it was at first thought that these were identical with a bacillus necroseos which produces necrotic and diphtheroid processes in several of the domestic animals, but subsequent observations have failed to confirm this view. A fusiform bacillus like that found in Vincent's angina has been discovered in cases of noma, either alone or in association with other organisms, by numerous observers. In a similar manner the diphtheria bacillus has been found not infrequently in cases of gangrenous stomatitis and vulvitis, sometimes associated with other bacilli. Various pyogenic organisms have also been found in cases of this disease and it has been suggested by Comba that the gangrene is not the result of the action of any specific organisms but that it may result from the presence of any pyogenic agent when its virulence is enhanced by the simultaneous growth of symbiotic organisms. A similar conclusion has been arrived at by Durante, who found staphylococcus pyogenes aureus with bacillus proteus vulgaris in a case of noma, and by Ravenna, who found the staphylococcus and the typhoid bacillus in another case. Dr. Hellesen quotes several other observers who have described organisms in this disease, the nature of which it is difficult to determine exactly; these comprise cocci and bacilli, both Gram-positive and Gram-negative, some of which appeared to be capable of producing necrotic processes in animals. Dr. Hellesen investigated the case alluded to above with great care by means of cultures made from the necrotic tissues, inoculation experiments both with these cultures and with the necrotic tissue, and microscopical examination of sections of the latter. The patient was a boy, aged three and a half years, who suffered from measles in the month of May, 1905, but recovered completely. In August of the same year he developed some swelling of the right cheek which increased, causing considerable swelling of the side of the face, some fever, and great pain. After a few days ulceration commenced on the inner side of the cheek, associated with intense fœtor. The urine contained neither albumin nor sugar. The general condition of the child was good and he was well nourished. The cheek became gangrenous and the process spread to the gums. Death occurred about three weeks from the commencement of the process. Cover-glass preparations made from the gangrenous tissue showed numerous cocci, including diplococci and short rods, and a few fusiform bacilli and spirilla. Plate cultures were made, with the result that the cocci proved to be staphylococci and streptococci of ordinary characters. The bacilli were short and were decolourised by Gram's method but were not further investigated. The diplococci were isolated and their cultural and tinctorial characters were carefully investigated. They resembled the pneumococcus in shape and size but did not possess any capsule. They stained well with the ordinary aniline stains and also by Gram's method. They rendered bouillon turbid and in 24 hours produced an acid reaction in it. Upon agar slopes they produced punctate, whitish-grey, translucent colonies in 24 hours. They coagulated milk in 24 hours and here again developed an acid reaction. They grew well in grape-sugar agar without forming gas. Cultures made from the blood both before and after death yielded diplococci identical in character and no other organism. The same diplococcus was invariably found in sections made from the affected tissues, not only in the necrotic areas but also in the area of infiltration around them and even in the apparently healthy tissue adjacent. On inoculation into animals a typical and apparently a specific necrosis was produced both by means of the gangrenous tissue and the cultures of diplococci. In these experiments the diplococci could be recovered from the necrotic areas and from the blood. The virulence of the organism became weakened if repeatedly transferred to fresh bouillon; on the other hand, growth with other organisms rendered it more active. Dr. Hellesen concludes that the diplococcus isolated by him was the pathogenic agent in the case under his care but is of opinion that the view expressed by other observers that noma is not a specific process and is not always produced by the same organism is most probably correct. This paper is one of great value, not only from the thorough way in which he investigated his case but also from the interesting *résumé* which he has given of previous observations on the subject.

THE UNIVERSITY OF LONDON UNION SOCIETY.

THE friends of the University of London both before and since its reconstitution have always felt that if it is to attain a proper solidarity and to lay the foundation of a "tradition," which, in the nature of things, none but its future generations can hope to feel as a guiding force, advances must be made along other lines than the purely academic. A community of social interests must be fostered which will afford opportunity of good-fellowship amongst its scattered members, such as is not to be found in lecture-room or examination hall. That such a spirit is stirring is evident from the report for 1907 of the University of London

MEDICINE AND THE LAW.

Prosecutions for Sending Indecent Matter by Post.

ON March 17th two prosecutions took place at Bow-street police court, under the Post Office Protection Act, 1884, for sending indecent matter through the post. In the first the defendant was Robert S. Sievier, editor of a sporting newspaper, the *Winning Post*, which has lately attracted to itself attention by publishing on its first page paragraphs and anecdotes of such a character that even the defendant could not have expected legal proceedings in respect of them to be delayed much longer. It was urged in his defence that the *Winning Post* was a sporting publication, the principal contents of which commended it to bookmakers and others addicted to racing and kindred pursuits and that the morals of such persons were not likely to be rendered worse by reading paragraphs of the kind in question (a line of defence which surely libels the racing public). At the same time, it was stated that the defendant was willing to discontinue the matter complained of if it were thought that there were people who bought the paper and who were likely to be offended. The magistrate, Mr. Marsham, in convicting the defendant, whom he fined £10 with £5 5*s.* costs, spoke of the *Winning Post* as a good sporting paper, the tone of which was spoilt and its value deteriorated by paragraphs such as those which formed the subject of the prosecution. In this case the newspaper was, and is, published in the usual manner and recourse had been had to the Post Office Protection Act apparently as a matter of convenience, a detective having written to the publisher in consequence of complaints received and having thereby obtained through the post the copies produced in evidence. The second prosecution to which reference has been made was a more genuine instance of the usefulness of the statute. The defendants were the Cardinal Manufacturing Company (Limited), of Wilson-street, Finsbury, which had sent through the post a mass of indecent matter addressed to a married lady who had recently borne a child and had announced the birth in the usual manner in the newspapers. It so happened that her husband was a medical man who, naturally incensed by such conduct, had the courage and public spirit to set on foot proceedings against those responsible, with a view to protecting himself and others, if possible, against a repetition of it. He is to be congratulated upon the result of his action, as the company was convicted and fined £10 with £5 5*s.* costs. In commenting upon these two cases it may be said fairly that both convictions were deserved, but that whereas none need endeavour to minimise the harm done by obscene innuendoes put in a form intended to raise mirth among the more brutalised of the readers of a sporting newspaper, the other class of obscenity referred to represents a more insidious form of corruption of the mental and bodily health of the public. The forwarding by post of advertisements intended to enable the limitation of families may be an outcome of prosecutions which have cleared the pages of respectable newspapers of the invitations of the quack abortionist and his tribe. There has been great improvement in this respect, and no doubt there is a large class of persons who cannot be reached as easily as at one time was possible. It must not, however, be supposed for a moment that these very objectionable advertisements do not now appear anywhere in public prints. We have before us a copy of *Photo Bits*, a publication selected at random owing to the vulgarity of its illustrations and general contents, as one apparently appealing to a class likely to be allured and corrupted. On the last pages of the number under notice appear no less than 13 advertisements of "rubber goods," which, we believe, would not be permitted in a public urinal, six advertisements directed expressly to married persons, and about the same number addressed to "ladies" and "females," the character of all of which is obvious. We do not suggest that all these advertisements emanate from different firms; it is fairly plain that several of them are from the same source although different addresses are used. We do not pretend that all are of equal flagrancy but we note that in one the removal of the familiar "obstructions arising from any cause whatever" is promised, and the names of this and of other advertisers have been frequently seen appended to paragraphs which might well have commended them to the observation of the police. All advertisements such as we have described above are of a character discreditable to the newspaper which inserts them, and some of them suggest the desirability of close scrutiny of the trade sought to be furthered by them. The possible liability of the newspaper inserting them might also be considered seriously by those responsible for its production. There is no need to comment upon the fallacies underlying the suggestion made in the *Winning Post* case to the effect that indecent matter is blameless if laid before indecent-minded people because it cannot make them worse than they are already, but we would place to the credit of the sporting weekly that no advertisements of the class criticised defile its pages.

Mr. Plowden and the Evidence of Divisional Surgeons of Police.

At Marlborough-street police court recently Mr. Plowden expressed disapproval with regard to what he considered the unduly large number of cases before him in which the divisional surgeon had been summoned to examine persons arrested upon charges of drunkenness. This course was apparently adopted by the police on all occasions when the person arrested denied being drunk. Mr. Plowden said, according to the report published in the *Daily Telegraph*, that "such a frequent calling upon the doctor was putting him in the magistrate's place. It was for a magistrate to say whether a prisoner was drunk or not, and sending for a medical man in this way was simply paralysing justice. The medical fees were out of all proportion to the fines in these cases and he should disallow the fees in imposing fines in all cases where the medical man had been sent for on shallow grounds." Mr. Plowden then proceeded to ask the prisoners in turn whether they had asked for a medical man to be summoned or had consented to be examined by him, and when they said that they had done so he added the fee to the fine, but disallowed it when they said otherwise. It would not be easy for Mr. Plowden to justify any such statement as that with which he is credited above. It is for the magistrate to convict or to acquit the prisoner on the evidence before him and to punish him if he finds him guilty, and it is usually considered desirable that the decision whether for or against the prisoner should be founded upon the best evidence obtainable. If the evidence of a medical man is not the best evidence obtainable it is difficult to explain why Mr. Plowden should attach so much weight to it that he feels practically bound to decide in accordance with it—which is apparently the meaning of his saying that sending for a medical man was "paralysing justice." If the persons charged with drunkenness deny being drunk at the time of their arrest the police cannot possibly prophesy whether on the following morning they will claim to have been sober the night before and accuse the police of misconduct or will admit the charge against them, and in fairness to their prisoners and to themselves they call in the assistance of an independent expert. To convict a man in the morning of drunkenness and at the same time to accept his statement as to what he said the night before when drunk and excited by arrest is also hardly logical. The medical man, whether a police surgeon or not, is an expert whose evidence is less liable to the suggestion of bias than that of the constable who effected the arrest or that of the officer in charge of the police-station who orders the prisoner to be placed in a cell. The medical man is not "put in the magistrate's place"; he is called in in order that he may form and give an opinion upon a question which may be in dispute and he expresses that opinion in the witness-box in addition to, or in contradiction of, the evidence of the police and of other witnesses according as the facts under his observation may require. If he is "put in the magistrate's place" by being sent for, then the umour of about the size of the fœtal head, very moveable and fluctuating. A diagnosis of ovarian cyst was made and was confirmed on operation. The cyst had a long narrow pedicle but was free from adhesions. It was easily drawn outside the abdomen after puncture and the pedicle was ligatured with kangaroo tendon. The operation lasted 20 minutes and recovery was uneventful. At no time did the pulse rise above 80 or the temperature above normal. She was allowed to sit up on the twelfth day. On the twentieth day after operation, after being dressed and seated in a chair, she suddenly developed dyspnœa without any warning. She became cyanotic and unconscious and the pulse became so small that it could not be counted and she died in ten minutes. At the necropsy the peritoneum was found to be perfectly normal; the omentum was slightly adherent to the abdominal incision. The stump of the pedicle was in perfect condition. The diaphragm was high on both sides, reaching the lower border of the fourth ribs. The right lung was contracted and at the junction of the middle with the lower lobe showed a dark subpleural discolouration. On section the lung was found still to contain air, to be of a brownish-red hue, and to contain a little blood. A large branch of the pulmonary artery supplying the lower portion of the lung contained fresh brownish thrombi slightly adherent to the vessel walls. Corresponding to the discolouration described was a black focus of about the size of a hen's egg. The left lung was similar to the right; it was somewhat collapsed and of a dark brownish-red hue. The large branches of the pulmonary artery were thrombosed. The heart was somewhat enlarged and the muscle was soft and reddish-yellow.

THE SIXTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

THE Sixteenth International Congress of Medicine will be held at Budapest from August 29th to Sept. 4th, 1909, under the august patronage of H.I.M. Francis Joseph, Emperor of Austria. The President of the Congress will be Professor C. Müller and the Secretary-General Dr. Emil Grósz. The president of the national committee for Great Britain is Dr. F. W. Pavy, and the secretary Mr. D'Arcy Power. The work will be carried out in 21 sections, with one subsection (of orthopædics), each with its own president and secretary, and although an elaborate provisional programme of proceedings has been issued already, offers from medical men to contribute papers are now being solicited by circular; we do not find many British names in the preliminary list. At both plenary and sectional sittings the English, French, German, or Italian language may be employed. The full programme of the papers to be read will be published by the end of the present year, and manuscripts of such papers, which must be clearly written, are to be sent to the Bureau du XVI^{e} Congrès International de Médecine, Esterházy-utcza 7, Budapest VIII., Hungary, by Jan. 31st, 1909, at the latest, so that members of the sections may receive printed copies before the Congress opens. The time for reading each paper is limited to 20 minutes. Discussion is limited to ten minutes for each speaker. The subscription for each member is 25 crowns (£1), which will entitle him to take part in the business of any section and to receive the literature of the section to which he has attached himself. Facilities for reduced fares will be obtained from the principal railways concerned. Wives and daughters of members will have similar advantages on a payment of half the subscription for each. Subscriptions are to be sent to the treasurer of the Congress (M. le Trésorier du XVI^{e} Congrès International de Médecine, Esterházy-utcza 7, Budapest VIII.), with an intimation as to the section to which the member wishes to be attached. Intending members are asked to send at the same time a card on which the applicant's position and full private address are legibly inscribed. Subsequent changes of address should be notified without delay. All further information can be obtained from the general secretary at the Bureau of the Congress.

THE TREATMENT OF CHRONIC ULCER OF THE LEG.

ABOUT 20 years ago Professor Unna of Hamburg devised a method of treating ulcers of the leg which proved very successful in his hands and has quite recently been strongly recommended by Dr. H. Hecker of Strassburg in an address delivered at a meeting of the Medical Society of Lower Alsace. The principal feature of the treatment is the use of an adhesive zinc dressing (*Zinkleimverband*), and full details relating to it were given by Dr. Hecker in his address which has been published in the *Strassburger Medizinische Zeitung* (No. 2, 1908). The basis of the dressing is formed by mixing gradually in a water-bath with constant stirring 40 grammes of glycerine, 40 grammes of water, 10 grammes of gelatin in small pieces, and 10 grammes of oxide of zinc. This mixture solidifies on cooling; it may be kept for any length of time in a tin box and is liquefied by warming when required. Bandages moistened with solutions of antiseptics such as lysol or chinosol are first of all applied to the ulcer in order to cleanse it and to reduce the irritability of the surrounding parts. The skin of the whole leg is then thoroughly cleansed with soap and water, shaved, and freed from greasiness by means of ether, so that the dressing may adhere readily to it. The skin of the whole leg is next brushed over with the above-mentioned warm mixture applied with a stout hair pencil, after which the ulcer is covered with antiseptic powder to such a depth that the surface is no longer visible. A variety of powders may be used for this purpose, airol being the one preferred by Dr. Hecker. When the ulcer has received its coating of powder it is covered with a layer of wadding free from grease and overlapping the edges of the ulcer in all directions for a distance of two or three centimetres. The interposition of protective silk or guttapercha tissue between the ulcer and the wadding is unnecessary and has the disadvantage of preventing the absorption of the discharge by the wadding. The parts of the foot and leg where the bandage exerts most pressure are also protected with wadding. For bandaging the limb two starched gauze bandages are required, each ten centimetres wide and ten metres long and rolled in two halves from each end to the middle. The bandages having been wetted with water and well squeezed out the foot is bandaged from the ankle to the toes, which are left uncovered, and the process is continued in the reverse direction, each turn overlapping half of the previous one, until it comes to a hand's breadth below the knee. The second bandage is then applied in exactly the same way over the first one. The size of the ulcer makes no difference in the treatment. Even the largest ones, almost quite surrounding the leg, can be made to heal by this simple means. The leg must now be kept in the horizontal position either exposed to the heat of the sun or near a stove; it must not be covered with stocking, trousers, or bedclothes until the bandage is quite hard. The dressings are not usually changed until after the lapse of three weeks. This may be necessary at an earlier date if the discharge is so profuse as to soak through the bandage, but if the discharge is scanty the whole may be left undisturbed for four weeks. The bandage is best slit up with shears but it may also be unwound after wetting with warm water. In changing the dressings the ulcer must not be left uncovered long enough to become dry. One advantage of this treatment is that the patients may walk about and follow their usual occupations during the whole course of it. The resulting scar is of firm consistence and far more a copy of the Local Government Board's circular should be forwarded to every medical practitioner in England and Wales in a modified form. They had omitted the names of those medical practitioners residing in certain streets in the large towns, where only consultants could be reasonably expected to be found. In addition to this, the matter had been the subject of continual conversation between the officials of the Privy Council on the one side and the chairman and the secretary of the Board on the other. The point that ought to be understood was that the omission in the Act could only be cured by fresh legislation, and although that had been repeatedly urged upon the Privy Council, it had not hitherto seen its way to undertake it. The Board therefore had not neglected its duties in regard to that subject. Mr. Parker Young took a gloomy view about the Midwives Act being unworkable; in a sense it was so, but in spite of certain clogs on its wheels the Act had been worked, though they all agreed it was not working as it ought to. Midwives must be supplemented and medical men must be paid and when that was done it would not be a long time before it would be a profitable expenditure and would put money in the pockets of the country by securing the health of the women and the children. The Central Midwives Board must indicate to the proper authorities in what way the Act can be amended. A step in the right direction had been made by the issue of the circular of the Local Government Board and it was of great importance because a great principle was thus accepted.

Mr. WARD COUSINS said the Board had not done enough and the difficulty had not been overcome which rendered the working of the Act impossible.

Dr. CHAMPNEYS here explained that it must not be understood that he was in any way opposed to the motion proposed by Mr. Ward Cousins.

Mr. WARD COUSINS, resuming, said that if the Board voted for the motion then the Board must interview Mr. John Burns.

The motion was then put with the addition mentioned above and was carried unanimously.

The question of formulating definite proposals to be submitted to the Privy Council and the Local Government Board was referred to the Standing Committee.

A letter was received from the Under Secretary of State for the Home Department informing the Board that the chief constables of counties and boroughs and the commissioners of police of the metropolis and of the City of London had been requested to report convictions of midwives directly to the Board.

A letter was received from the Clerk of the Privy Council stating that the Treasury had authorised the Controller of His Majesty's Stationery Office to arrange with the Board for the supply of copies of the Midwives Roll of 1908 and to distribute the same to the coroners of England and Wales.

A letter was considered from the Devon and Cornwall Training School for Nurses asking the Board to hold an examination at Plymouth. It was decided that the request should be refused, the probable number of candidates being at present insufficient to warrant the holding of an examination at Plymouth, but when 20 candidates can be guaranteed the Board would reconsider the matter.

A letter was considered from the clerk of the London County Council as to the construction of Rule E 26, and it was decided that the London County Council should be informed that the amendment of Rule E 26 having been dealt with the Board does not propose to reopen the question at present.

A letter was received from the registrar of the General Medical Council concerning the communication made to it by the Board with reference to the late master of the Coombe Hospital, Dublin, stating that the Council did not propose to take any steps in the matter. A letter was received from the registrar of the Coombe Hospital, Dublin, forwarding a copy of a resolution passed by the board of governors of the hospital requesting the Central Midwives Board to reinstate the Coombe Hospital as an approved training school, and it was decided that the request should be granted and that the name of the Coombe Hospital, Dublin, should be replaced on the list of approved training schools. The chairman also stated that the Central Midwives Board had reason to be satisfied with the straightforward way in which the authorities of Coombe Hospital had met the Board in regard to their representations.

A letter was considered from Dr. H. Handford, county medical officer of Notts, as to the construction of Rules E 1 and 5 which deal with directions to midwives concerning their duties to patient and child and their obligations with regard to disinfection, &c. It was decided that Dr. Handford should be informed that the case of a midwife suffering from septic ulcers or kindred complaints appears to fall within the terms of Rules E 1 and 5, or might be dealt with by the local sanitary authority under the Public Health Acts.

On the question of the training and supply of midwives the Board affirmed the following propositions and decided to forward a copy of them to the Privy Council:—

1. That midwives (who are "a necessity") will be unable to make a living in many localities without extraneous aid.
2. That such localities are very often exactly those in which their presence is most necessary from the poverty and (in some cases) the sparseness of the population.
3. That voluntary contributions cannot be relied upon to supply the whole of the necessary financial aid.
4. That for this purpose a Government grant is a necessity.
5. That if such a grant were provided a representative council of competent persons should be appointed to administer the fund thus constituted.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on Friday, March 20th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

Licences to practise physic were granted to Bertram Arthur Lloyd, Birmingham University, and David Ranken, Durham University.

The following communications were received:—1. Three communications from the secretary of the Royal College of Surgeons of England reporting proceedings of the Council. One of these conveyed a proposal that the committees which have been separately appointed by the two Colleges on the subject of the medical inspection of school children and the teaching of hygiene should act together to form a joint committee. The proposal was agreed to. The physicians appointed are Sir W. S. Church, Dr. G. A. Heron, Sir Lauder Brunton, Dr. B. L. Abrahams, and Dr. W. H. Hamer. 2. From Dr. H. Cooper Pattin, medical officer of health of the city of Norwich, asking leave to have a sketch made from one of the portraits of Dr. Caius in the College for a medallion by a London sculptor. The request was granted. 3. From the secretary of the International Congress on Laryngology and Rhinology with a Türck-Czermak commemoration, to be held in Vienna on April 21st to 25th, 1908, inviting the College to send a delegate. The invitation was accepted and Sir Felix Semon was appointed to represent the College.

The Harveian Librarian (Dr. J. F. PAYNE) proposed, and the Treasurer (Sir DYCE DUCKWORTH) seconded, the following motion:—

> That in pursuance of a resolution adopted at the meeting of the library committee, January 23rd last, a commencement be made of preparing a new printed catalogue of the College library.

The motion was adopted.

A report, dated March 3rd, was received from the committee of management. The report, which was adopted, recommended that University College School, Frognal, Hampstead, should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics.

The PRESIDENT then dissolved the Comitia.

A LINK WITH THE PAST.—The late Mr. John Joseph Ayre, M.R.C.S. Eng., L.S.A., of Eastlemes, Colne, Lancashire, whose death has been recently announced at the age of 96 years, was educated at King's College, London, and became a Licentiate of the Society of Apothecaries in 1832. He received the Membership of the Royal College of Surgeons of England in 1859. He belonged to a family which contributed several of its members to the medical profession. His father was Dr. John Ayre, and his uncle, with whom he was brought up, was Dr. Joseph Ayre, a physician of repute in London. Mr. Ayre lived during five reigns and told with interest his experiences as a medical practitioner during the long period over which his active work extended. Till the end of his life Mr. Ayre took an intellectual interest in all scientific discovery.

THE METHOD OF PREPARING "NEW TUBERCULIN" (TUBERCULIN T.R.): A CORRECTION.

BY PROFESSOR W. G. RUPPEL.[1]

(*Translated for* THE LANCET.)

IN his well-known article entitled "New Tuberculin Preparations" which appeared in No. 14 of the *Deutsche Medizinische Wochenschrift* in the year 1897, Professor Robert Koch referred to the endeavours which had been made to discover a specific remedy for tuberculosis and discussed his reasons for believing that the discovery of tuberculin did not mark the final limit of these endeavours. In tuberculin Koch had found a substance which on the one hand enabled tuberculosis to be diagnosed with certainty even in the earliest stages of the disease, and on the other hand exercised a perceptible influence on tuberculous processes. The therapeutic value of tuberculin was at the same time practically established. The only obstacle to the general employment of tuberculin as a remedy was the frequent occurrence of violent reactions. Koch's efforts were therefore directed to the preparation of substances which would possess the immunising and curative properties of tuberculin but would not set up an intense general reaction in tuberculous subjects inoculated with them. Such substances, he thought, must be looked for in the material of which the tubercle bacillus is composed.

Many attempts to immunize animals with the help of dead tubercle bacilli led to no satisfactory result. This failure was attributed to the fact that dead tubercle bacilli injected subcutaneously were not properly absorbed by the deep layers of the skin but gave rise to the formation of abscesses. When injected into the veins, however, the dead bacilli were deposited in the lungs where they brought about pathological changes exactly similar to those produced by bacilli which were alive and capable of propagation; these changes were therefore genuine pulmonary tubercles. This being so it became necessary to convert the tubercle bacilli into a form in which they would be absorbed. In this process chemical agents had to be avoided, because there was reason to fear that they would have an injurious effect on the immunising substances of the tubercle bacilli. After many experiments Koch by means of a purely mechanical method succeeded in breaking up the bacilli and converting them into a form capable of absorption. For this purpose they were strongly dried and rubbed in an agate mortar into a powder so fine that entire tubercle bacilli capable of characteristic staining could no longer be seen in it under the microscope. By extraction with distilled water all the soluble matter could be removed from the tubercle bacilli which had been rubbed in the mortar, and the resulting solution when freed from the insoluble residue by centrifugalising is a slightly opalescent but quite clear fluid. Koch denoted it by the initials T.O. It contains the toxic constituents of the tubercle bacilli. Its action upon tuberculous patients and animals is analogous to the action of the old tuberculin. Admixture of an equal amount of glycerine with T.O. does not throw down a precipitate, showing that T.O., like old tuberculin, contains such portions of the tubercle bacilli as are soluble in glycerine.

The whole of the insoluble residue which has been freed from T.O. by centrifugalising can by appropriate treatment, many times repeated, be converted into a series of solutions. This treatment consists in successively drying the substance thoroughly, rubbing it in a mortar, extracting with water, and centrifugalising. These solutions may be regarded as possessing identical properties. Unlike T.O., they contain substances which are precipitable by 50 per cent. glycerine and which produce only a small toxic effect on tuberculous individuals. These solutions are called by Koch the residual portion of the tubercle bacilli (*Tuberkelbazillenrückstand*) and are denoted by the abbreviation T.R. The whole of the immunising substances present in the tubercle bacilli are contained in these solutions in a form perfectly capable of absorption by the organism.

In the above-quoted article Koch draws attention to the difficulties and dangers associated with the working up of tubercle bacilli in the preparation of T.O. and T.R., and mentions that for this purpose it is necessary to have such mechanical appliances as are only used in a factory. He has therefore intrusted the manufacture of these preparations to the firm known as the Farbwerke vorm. Meister, Lucius, and Brüning in Höchst on the Main. Since the year 1897 these preparations have been manufactured in the bacteriological department of this establishment, where Koch's directions are most carefully observed.

In a particular instance the process of manufacture is as follows. One gramme of strongly dried tubercle bacilli is pulverised in a suitable apparatus until entire tubercle bacilli are no longer recognisable in a sample. The pulverised mass is then treated with 100 cubic centimetres of sterile distilled water and centrifugalised. The result of this operation is a fluid which is called T.O. and an insoluble residue which is called T.R.I. The latter is now strongly dried, pulverised, treated with water, and centrifugalised, yielding for the second time a solution and a solid residue. The residue is again dried, pulverised, treated with water, and centrifugalised. It is found that by two or three repetitions of this process the whole of the insoluble residue T.R.I. originally obtained on the removal of the T.O. can be converted into a series of solutions without any insoluble matter remaining at last except accidental mechanical impurities. All these solutions are now combined. In the successive conversion of the T.R.I. into a series of solutions care must be taken that the total volume of the combined fluids shall be less than 100 cubic centimetres. The amount of solid substance present in it is ascertained by submitting a small portion (five cubic centimetres) to a dry process—namely, evaporation *in vacuo* and weighing. To the rest of the fluid there are now added a little glycerine and formaldehyde and finally a sufficiency of water to make one cubic centimetre contain exactly 0·002 gramme of dry residue. The T.R. is now quite ready. For the preparation of tuberculin T.R. we always make use of the same culture which is grown upon a special nutrient medium of constant composition. Commencing in this way the preparation of the tuberculin T.R. proceeds quite uniformly, so that approximately 100 cubic centimetres of T.R. are always obtained from one gramme of dried tubercle bacilli. These 100 cubic centimetres of T.R. therefore contain according to Koch's view the immunising substance of one gramme of dried bacilli. One cubic centimetre of T.R. therefore corresponds to 10 milligrammes of dried bacilli, but 100 cubic centimetres of T.R. in reality contain only 0·2 gramme of dry constituent and one cubic centimetre therefore contains only 0·002 gramme, or two milligrammes of dry constituent.

In his above-quoted article Koch gives the following detailed instructions for the clinical use of T.R.:—

> The fluid contains 10 milligrammes of solids per cubic centimetre (*im ccm 10 mg fester Substanz*) and for use it must be brought to the required dose by dilution with physiological solution of common salt, not with carbolic acid solution. A beginning is made with $\frac{1}{500}$th of a milligramme.

From the above full description of the method of preparation it follows that Koch's expression, "the fluid contains 10 milligrammes of solids per cubic centimetre," must be understood to mean "one cubic centimetre contains the active or immunising substance of 10 milligrammes of dried tubercle bacilli." Consequently in beginning a course of tuberculin treatment with an initial dose of T.R., which, as Koch's directions require, corresponds to $\frac{1}{500}$th of a milligramme of tubercle bacilli, it is necessary to dilute the T.R. to such an extent that the operator may inject $\frac{1}{5000}$th (0·0002) of a cubic centimetre of the original fluid.

Practical experience has shown that dilution is best effected with a 20 per cent. solution of glycerine. With this there is no fear of precipitating the solid constituents of the T.R. because it has been stated above that they are not precipitated until the addition amounts to 50 per cent. of glycerine. This solution, hereinafter called glycerine water, is prepared by mixing 20 cubic centimetres of pure glycerine with 80 cubic centimetres of distilled water and boiling for 20 minutes. The fluid must be quite cold when used. The operator takes 0·3 cubic centimetre of tuberculin T.R. from an original bottle with a pipette divided into tenths of a cubic centimetre and adds to it 2·7 cubic centimetres of glycerine water. This gives a dilution of 10 per cent. strength (*eine 10 procentige Verdünnung*). Of this fluid 0·1 cubic centimetre is added to 9·0 cubic centimetres of glycerine water. This gives a thousandfold dilution, and of this 0·2 cubic centimetre or two divisions of a Koch syringe

---

[1] From the Bacteriological Department of the Farbwerke at Höchst am Main.

13 deaths attributed to diarrhœa, six occurred in Glasgow, four in Dundee, and two in Aberdeen. Three of the five fatal cases of scarlet fever were returned in Glasgow. The three deaths referred to "fever" showed a marked decline from recent weekly numbers, and were fewer than in any previous week of this year; of the two in Glasgow, one was certified as enteric and one as cerebro-spinal meningitis; the one in Leith was due to cerebro-spinal meningitis. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 156 and 142 in the two preceding weeks, rose again to 158 in the week under notice, and exceeded by 11 the number returned in the corresponding week of last year. The causes of 14, or 2·1 per cent., of the deaths in these eight towns last week were not certified; in the 76 English towns the proportion of uncertified causes of death in the same week did not exceed 1·1 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 24·1 and 24·8 per 1000 in the two preceding weeks, declined to 23·9 in the week ending March 21st. During the first 12 weeks of the current quarter the death-rate in the city averaged 25·3 per 1000, the mean rates during the same period being only 17·7 in London and 18·4 in Edinburgh. The 181 deaths of Dublin residents registered in the week under notice showed a decline of seven from the number returned in the previous week, and included but four which were referred to the principal epidemic diseases, corresponding with the number in the preceding week; these four deaths included one each from measles, scarlet fever, whooping-cough, and "fever," while no death resulted from diphtheria, diarrhœa, or small-pox. These four deaths were equal to an annual rate of but 0·5 per 1000, the death-rate last week from these principal epidemic diseases being equal to 1·1 in London and to 1·3 in Edinburgh. The 181 deaths from all causes in Dublin last week included 26 of infants under one year of age and 63 of persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons exceeded those returned in recent weeks. Two inquest cases but no deaths from violence were registered, and 95, or 52·5 per cent., of the deaths occurred in public institutions. The causes of four, or 2·2 per cent., of the deaths in Dublin last week were not certified; in London all but one of the 1455 causes of death were duly certified, while in Edinburgh the proportion of uncertified deaths was 4·0 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Surgeon Herbert Lyne Geoghegan has been promoted to the rank of Staff Surgeon in His Majesty's Fleet (dated May 15th, 1907).

The following appointments are notified:—Fleet Surgeons: R. Miller to the *President*, additional, temporarily. Surgeon: E. A. G. Wilkinson to the *Racer* for Osborne College. Civil Practitioner: D. Hadden, appointed surgeon and agent at Wexford.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Charles W. Thiele retires on retired pay (dated March 21st, 1908).

Lieutenant-Colonel W. Rowney has been appointed to the medical charge of the Connaught Hospital, North Camp, Aldershot. Lieutenant-Colonel H. J. Barratt has been appointed to medical charge at Shorncliffe. Major W. H. Horrocks has been appointed sanitary officer in London.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Edgar W. Livesey to be Surgeon-Major (dated March 14th, 1908).

IMPERIAL YEOMANRY.

Royal East Kent (The Duke of Connaught's Own): Campbell Tilbury Fox to be Surgeon-Lieutenant (dated Feb. 28th, 1908). Northamptonshire: Surgeon-Lieutenant Edward M. Knott resigns his commission (dated Feb. 24th, 1908).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): The Highland: Surgeon-Major J. M. Moir to be Surgeon-Lieutenant-Colonel (dated Feb. 10th, 1908). 2nd Lancashire: Surgeon-Captain Thomas Stevenson to be Surgeon-Major (dated March 3rd, 1908).

Rifle: 7th (Isle of Man) Volunteer Battalion, The King's (Liverpool Regiment): Surgeon-Captain William Richardson to be Surgeon-Major (dated Feb. 13th, 1908). 2nd (Prince of Wales's) Volunteer Battalion, The Devonshire Regiment: Surgeon-Captain Ernest P. A. Mariette to be Surgeon-Major (dated Feb. 18th, 1908). 1st Cinque Ports Volunteer Rifle Corps: Alfred Alexander to be Surgeon-Lieutenant (dated Feb. 24th, 1908). 1st Volunteer Battalion, The Durham Light Infantry: Douglas Vercoe Haig to be Surgeon-Lieutenant (dated Jan. 30th, 1908); David Leonard Fisher to be Surgeon-Lieutenant (dated Jan. 31st, 1908); George Greig Farquhar to be Surgeon-Lieutenant (dated Feb. 1st, 1908).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

London District: London Companies: George Langrigg Leathes Lawson (late Surgeon-Captain, 6th Regiment, Imperial Bushmen, New South Wales) to be Lieutenant (dated June 1st, 1907).

ROYAL VISIT TO MILLBANK.

On March 20th the Queen, accompanied by the Dowager Empress of Russia and Princess Victoria, paid a surprise visit to the Royal Military Hospital and to the Royal Army College, Millbank. Lord Roberts, Sir Frederick Treves, Sir Alfred Keogh (Director-General of the Army Medical Service), and others received the Royal party, who carefully inspected all the buildings. In the pathological laboratory of the Royal Army Medical College Colonel Bruce, explained the work done in that department of the College.

THE ALEXANDRA MILITARY HOSPITAL.

The Alexandra Military Hospital at Cosham, which has recently been formally occupied, the projected Royal opening having been abandoned, will accommodate 220 patients. The new hospital is situated on the slopes of Portsdown Hill and will serve the Southern Military Division. It was built to replace Netley Hospital and the Station Hospital at Portsmouth.

Captain F. J. Brakenridge, R.A.M.C., has received the King's permission to accept and to wear the Imperial Ottoman Order of the Medjidieh of the Fourth Class which has been conferred upon him by the Khedive of Egypt in recognition of valuable services rendered.

It is announced that officers of the Royal Army Medical Corps cannot be considered regimental officers for the purpose of drawing detention allowances under Clause 1 of Indian Army Order No. 405 of 1907.

"Audi alteram partem."

CHANGES IN THE HEART DURING ADOLESCENCE.

To the Editor of THE LANCET.

SIR,—In a recent leading article you did me the honour to quote from my observations on the changes, in size and proportion, of the heart during the period of adolescence, published in the "Report of the Health of the Navy" for the year 1902. Permit me to add that further experience and investigation have convinced me that this condition is physiological rather than pathological and is much more common than is generally supposed. The present state of athletics in excelsis renders obvious the necessity of a vigilant observation on growing youths by their responsible medical advisers. Fortunately, our increased knowledge of the normal evolution of the heart and the disorders of its structures and mechanism indicates both a preventive hygiene and a rational therapeusis, if these cases are only taken in time. In my report I alluded to the following points which may interest some of your readers and which I submit to their judgment and criticism.

Since Hope in 1839 laid down that a certain class of cardiac murmurs were due to altered physical properties of the blood, to unfilled vessels, and modified velocity of current, his views were almost universally accepted until quite recent years, although Skoda in 1853 expressed some doubt that a depraved state of the blood should necessarily create thank you for your kind vote of thanks which you have so cordially received. I am indeed gratified at the present most satisfactory state of the Fund. These excellent results are due to the many good friends who support me and who carry out the hard work—and it is very hard work—of administering this large sum of money. It is impossible for me to express sufficiently my gratitude to them for all they do in helping the Fund.

The proceedings then closed.

LYNN THOMAS AND SKYRME FUND.

THE following list of subscriptions (up to March 20th) has been received from Mr. William Sheen, 2, St. Andrew's Crescent, Cardiff, who is acting as secretary to the Fund:—

Subscribers of Ten Guineas.

Sir Charles B. Ball, Dublin.
George Lenthal Cheatle, C.B., London.
W. T. Edwards, Cardiff.
W. Lloyd Edwards, Barry, Glam.
A. Pearce Gould, London.
W. Arbuthnot Lane, London.
G. H. Makins, C.B., London.
C. W. Mansell Moullin, London.
J. Rutherford Morison, Newcastle-on-Tyne.
J. H. Nicoll, Glasgow.
E. J. Parry, Pontycymmer, Glam.

Subscribers of Ten Pounds.

Robert Jones, Liverpool.
A. Garrod Thomas, Newport.

Subscribers of Six Guineas.

Honorary Staff of Stockport Infirmary, per E. Rayner, Stockport.

Subscribers of Five Guineas.

E. L. Adams, East Croydon.
Sir Lauder Brunton, London.
Edred M. Corner, London.
Henry Davy, Exeter.
A. Francis Dixon, Dublin.
W. Washington David, Llwynypia, Glam.
Sir H. M. Ellis, K.C.B., Director-General, Royal Navy.
T. D. Griffiths, Swansea.
R. W. Jones, Penrhiwceiber, Glam.
D. J. Jones, Pontypool, Mon.
R. Conway Joyce, Porth, Glam.
C. B. Keetley, London.
Pagan Lowe, Bath.
E. J. Maclean, Cardiff.
B. G. A. Moynihan, Leeds.
Edmund Owen, London.
William Osler, Oxford.
J. Powell, Newcastle Emlyn.
H. M. Rigby, London.
William Sheen, Cardiff.
A. H. Tubby, London.
W. E. Thomas, Ystrad, Glam.
J. Tatham Thompson, Cardiff.
T. W. Thomas, Caerphilly.
D. J. Williams, Llanelly.
H. P. Waterhouse, London.
Sinclair White, Sheffield.
J. L. W. Ward, Merthyr.

Subscribers of Five Pounds.

Anthony A. Bowlby, C.M.G., London.
Sir John Williams, Bart., K.C.V.O., Llanstephan, Carm.

Subscribers of Three Guineas.

W. F. Brook, Swansea.
H. G. Barling, Birmingham.
G. A. Brown, Tredegar, Mon.
E. R. Bickersteth, Liverpool.
C. A. Ballance, London.
A. E. Barker, London.
Andrew Clark, Uxbridge, Middlesex.
F. Richardson Cross, Bristol.
E. Goodall, Cardiff.
Honorary Staff, General Infirmary, Macclesfield (per J. B. Hughes).
J. Hutchinson, London.
J. Arnallt Jones, Aberavon, Glam.
Evan Jones, Aberdare.
Sir William Macewen, Glasgow.
D. Naunton Morgan, Gilfach Goch, Glam.
Medical Society, Watford (per Thomas Smith, hon. sec.)
D. R. Paterson, Cardiff.
D. T. Richards, Risca, Mon.
W. Mitchell Stevens, Cardiff.
Alexis Thomson, Edinburgh.
C. T. Vachell, Cardiff.
W. J. Williams, Middlesbro-on-Tees.

Subscribers of Two Guineas.

W. Alexander, Liverpool.
A. T. Blease, Altrincham, Cheshire.
H. B. Butler, Guildford.
James Berry, London.
H. Langley Browne, West Bromwich.
Sir Hector C. Cameron, Glasgow.
J. Cotter, Cork.
S. C. Cresswell, Dowlais.
H. H. Clutton, London.
J. Hopkin Davies, Port Talbot.
Howard Davies, Pontypridd.
R. T. E. Davies, New Tredegar, Mon.
E. Evans, Llanelly.
H. T. Evans, Blackwood, Mon.
D. T. Edwards, Taff's Well, Cardiff.
C. H. Golding-Bird, London.
W. J. Greer, Newport, Mon.
P. Rhys Griffiths, Cardiff.
J. Gutch, Ipswich.
W. S. Haughton, Dublin.
G. S. Hatton, Newcastle, Staffs.
W. Ll. Jones, Merthyr.
Surgeon-General Sir Alfred Keogh, K.C.B., Director-General, Army Medical Service.
F. W. Kent, Barry, Glam.
H. A. Latimer, Swansea.
A. J. Lawrence, Chepstow.
John Langton, London.
R. Clement Lucas, London.
J. A. Macdonald, Taunton.
G. A. Morton, Bristol.
J. W. Mulligan, Abersychan, Mon.
J. H. Morgan, London.
William Martin, Cardiff.
R. H. Mills-Roberts, Llanberis, N. Wales.
P. Macgregor, Huddersfield.
Sir R. Douglas Powell, Bart., K.C.V.O., London.
G. H. Percival, Northampton.
T. W. Parry, Ferndale, Glam.
R. J. Pye-Smith, Sheffield.
A. W. Mayo Robson, London.
D. Valentine Rees, Brecon.
J. Hugh Rees, Penarth, Glam.
W. D. Steel, Abergavenny.
R. Shingleton Smith, Bristol.
Sir Thornley Stoker, Dublin.
H. P. Symonds, Oxford.
R. Stirling, Perth.
B. Thornton, Margate.
D. J. Thomas, Bargoed, Mon.
H. R. Townsend, Cork.
W. Thelwall Thomas, Liverpool.
May Thorne, London.
T. J. Verrall, Brighton.

of two cases of pancreatitis with jaundice which I had the opportunity of investigating in Sir Thomas Fraser's wards in the Edinburgh Royal Infirmary. These cases were examined by me incidentally in the course of an extensive investigation into the clinical value of the pancreatic reaction in the urine (Cammidge). One of the cases was a patient with simple "catarrhal jaundice," the other was a case of malaria (malignant type) with jaundice. In each case a diagnosis of pancreatitis was made, from the association of (*a*) jaundice, (*b*) marked tenderness in the region of the head of the pancreas, and (*c*) a marked positive reaction in the urine by the pancreatic reaction. The results of my observations on these cases led me to conclude that the jaundice occasionally met with in malaria has its origin in pancreatic disease, and further that inflammation of the pancreas is an important factor in the development of simple "catarrhal jaundice." These views are in close accord with those expressed by Dr. Phillips, and in view of the clinical importance of the subject I have ventured to draw fresh attention to it.—I am, Sir, yours faithfully,

Edinburgh, March 22nd, 1908. CHALMERS WATSON.

THE STREAM HILL SANATORIUM SITE.

To the Editor of THE LANCET.

SIR,—In your issue of March 14th a letter appeared from Mr. Langley Brasier-Creagh, regarding the suitability of the Stream Hill site for a sanatorium for the county of Cork. As engineer appointed by the opposing ratepayers in the district of Buttevant and Doneraile to thoroughly examine the site and give evidence at the late Local Government Board inquiry I beg to say that, in my opinion, the site is utterly unsuitable for a sanatorium. The place is covered with patches of rushes, surface soil peat mould, and subsoil, most important of all, yellow marly clay, which is most retentive to moisture. I may add that I had a trial hole dug on the proposed site of the sanatorium building and found soil as described above, a sample of which I produced at the inquiry. I am, Sir, yours faithfully,

Killeagh, Co. Cork, March 21st, 1908. EDWIN GREEN, C.E.

INFLUENZA IN THE HOUSE OF COMMONS AND AN OPEN-AIR HALL.

To the Editor of THE LANCET.

SIR,—I should like to remind your readers that the experiment of an open-air hall for public gatherings is being already tried at Letchworth. An account of the building by the architect, illustrated by photographs, can be seen in the *Architectural Review* for March. We have encountered many difficulties, especially due to the exposed situation, and we have still various improvements to make. However, since the first week in January the hall has been in use, each week 50 or 60 people from Garden City sitting for an hour during an organ recital and an address in a hall which, though warmed by fires and hot-water pipes, is only protected from the open air on one side by tarpaulin and canvas curtains; these latter are removeable in fine weather. The building is also constructed, drained, and the floor fitted with corticene, so as to enable the place to be cleaned down regularly with a hose-pipe, thus avoiding any question of germs. I am, Sir, yours faithfully,

A. J. LAWRENCE.

PORT WINE AND ITS COUNTRY OF ORIGIN.

To the Editor of THE LANCET.

SIR,—A recent decision by a police-court magistrate to the effect that "port" in order to be port must come from Oporto reminds one of the old puzzle (which should have been cited on behalf of the prosecution): "Gdldprtfrmprtfrthdxxfrddns," which, we used to be told, needed but the addition of a single vowel in order to make it intelligible. The vowel was, of course, "o," repeated often enough to form the sentence: "Good old port from Oporto for orthodox Oxford dons." It was invented in days when port and Oxford dons alike were orthodox.

I am, Sir, yours faithfully,

A. A.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Walsall's New Sewage Scheme.

THE pressure brought to bear by the Local Government Board and the county council has compelled Walsall to face the question of a proper solution of its sewage problem. The desire of a town council to put off the adoption of a costly scheme is quite easy to understand in a period when taxes and rates are advancing in a way which is quite out of proportion to the returns from productive labour, but a proper sewage scheme has become a necessity and Walsall will have to face an increased rate of about 3*d.* in the £, for if the scheme be approved it will be necessary to ask the Local Government Board to sanction a loan of £62,734 to meet the costs, and the interest on that sum and other incidental expenses can only be met by an increased rate of 3*d.*

The Birmingham Industries Exhibition.

The object of the Birmingham Industries Exhibition which opens at the Bingley Hall to-day is to clear off the balance of the debt resulting from the purchasing, rebuilding, and equipping the Hospital Saturday Fund's convalescent home for women at Marble Hall, near Llandudno, to which some 1200 women and girls are sent every year. A sum of £4000 is necessary and at present there is every hope that the whole or the greater part will be secured, for the exhibition promises to be a great success. From its very constitution it will of necessity excite local interest and curiosity and an opportunity will be given to the visitors to hear excellent music, for the majority of the well-known bands of the country have been engaged to play in the hall during the weeks in which the exhibition will be open.

The Birmingham and Midland Hospital for Skin and Urinary Diseases.

During the year 1907 the number of in-patients treated in the above hospital was 184, or 19 more than in 1906, and the number of out-patients was 7317, showing an increase of 111 as compared with 1906. The total expenditure for the year was £2962 and it exceeded the income by a little more than £130. The committee states that unless the hospital can secure an increased annual income of £275 its work must be curtailed. In moving the adoption of the report the Lord Mayor remarked that he noticed that during the year 78 patients had been rejected in the out-patient department on the ground of their being able to pay for treatment, and he expressed the hope that very great consideration would be exercised before such rejections were made. With this hope the medical profession will be in cordial agreement, but it will also equally urge that every care should be taken that patients who can afford to pay shall not be treated gratuitously and that they shall not be taught to think that what sums they give as charitable aid to hospital funds are to be looked upon as club subscriptions entitling them to treatment.

March 23rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Ladies' Sanitary Association and Infantile Mortality.

THE Liverpool Ladies' Sanitary Association is endeavouring to raise a fund of £1500 to cope with the great waste caused by the appalling death-rate among infants and young children in the city. A suitable house has been purchased by the generosity of two ladies and will be used as a hostel for the children's nurses trained by the association. It will contain a day nursery where these nurses can obtain practical instruction in the care of infants. The association, in addition to the work of the hostel and day nursery, intends to send mothers' visitors out into the city to give advice and personal help to expectant mothers before confinement and to render some further assistance after midwives, medical men, or district nurses have ceased to visit these cases. A suitable matron has been engaged for the hostel and day nursery and it is intended to employ a trained lady to superintend the mothers' visitors. These mothers' visitors will have practical help in their work by magistrate should take the place of the medical man and cause himself to be sent for when drunkenness is disputed at the police station in order to form his opinion at the time and on the spot. Otherwise he has to form it next day upon the evidence of the less qualified of the witnesses available after having declined to allow better evidence within easy reach to be presented to him, a course more likely to "paralyse justice" than the summoning of a medical man in a few instances in which his presence is not absolutely necessary. The fact that a medical man in some cases of apparent drunkenness and in others where the prisoner is, in fact, intoxicated may be able to render valuable assistance is also one not to be lost sight of.

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at Caxton House, Westminster, on March 19th, Dr. F. H. CHAMPNEYS being in the chair.

Mr. J. WARD COUSINS moved the following :—

> That as no arrangement for the payment of fees to medical men summoned to assist certified midwives has been made satisfactory to the medical practitioners of the country, the time has arrived for the Board to reconsider the question, with special reference to the efficient operation of the Midwives Act, 1902.

He said that the Central Midwives Board should reconsider the question of payment to medical men summoned to assist certified midwives. All the great medical colleges and corporations, the British Medical Association, and the Society of Apothecaries were of opinion that the Board should reconsider the question. Up to the present time that Board had not achieved anything. They knew that certain places like Liverpool, Manchester, and Birmingham had arranged for the payment of fees to medical men summoned to assist certified midwives, but the Midwives Act extended over England and Wales and practically nothing had been done. No method of dealing with this question would be sufficient unless it applied to the whole of the area under the control of the Board. Medical men would never be satisfied with the partial suggestions contained in the circular of the Local Government Board dated July 29th, 1907, addressed to all boards of guardians. In that circular the Local Government Board intimated that if the guardians would only be kind and liberal and pay medical men called in by midwives if the guardians thought fit, then there would be an end to the difficulty and the medical men would have nothing to complain about. But there was *not* a single argument proving that those directions to the guardians were in any way satisfactory to the medical profession. His own feeling was that if anything was done it must be done by the Central Midwives Board. By the third section of the Midwives Act it was provided that the duties and powers of the Board were to do any act or duty which might be necessary for the due and proper carrying out of the provisions of the Act. He must, however, leave the exact legal meaning of those words to those who interpreted Acts of Parliament, but he maintained that it was absolutely impossible for the Act to be successfully carried out unless the difficulty in regard to the payment of medical men summoned by certain midwives was fairly met. He further wished to emphasise the fact that if the Act was not carried out it was the poor women and children of this country who would suffer. In 1910 all the old "Sairey Gamps" would be cut off from the practice of midwifery, and unless provision was made for the payment of medical men the certified midwives would be left without assistance, for it was absurd to expect medical men to attend cases for nothing. The suggestion that the difficulty could be met by an amendment of the Midwives Act was useless because there was not the slightest prospect of that coming about. It seemed to him, therefore, that the Central Midwives Board must find a solution of the difficulty and they must arrange for another interview with the Local Government Board to discuss the matter. He was quite sure that the idea of leaving the question of the payment of medical men to the boards of guardians was futile, for the boards of guardians would not think fit to pay the fees. From his experience of guardians if the question of a fee to a medical man was before them it would be discussed for hours and nothing would be done. The whole matter would assume a different aspect if the Local Government Board ordered boards of guardians to pay the fees of medical men, directing that the applications for such payments should be made to the guardians through the local supervising authorities. The important point was that the Central Midwives Board should draw up a fair scale of fees for medical men called in by certified midwives and then interview the Local Government Board and explain the difficulties attending the working of the Midwives Act. In that way a great deal of good would be produced, and he hoped by that means the breach between medical men and midwives would be healed.

Mr. E. PARKER YOUNG, in seconding the motion, said that the Government ought to take the matter up. The Act ought to act smoothly instead of being, as it was at present, unworkable. The Government ought to make proper provision for the payment of medical men and the matter ought not to be left to the decision of guardians whether they thought fit to pay or not. If the motion was carried they could go to Mr. John Burns, who was a fair man, and discuss it with him.

Dr. STANLEY B. ATKINSON suggested that the words "and certified midwives" should be added after the word "practitioners," and this was accepted by the mover and seconder of the motion.

Dr. CHAMPNEYS *said that they had reason to be grateful to* the Local Government Board for issuing the circular of July 29th, 1907. The circular did not solve the whole question, but that was another matter ; at any rate it was a recognition that something ought to be done. He then proceeded to read out the circular of the Local Government Board of July 29th, and said it was a document that could not be passed over as unsatisfactory and it ought to be known to medical men. More was required than had been done but it was not in accordance with facts to state that the Central Midwives Board had not done anything in regard to this question of payment of medical men. The following record taken by the secretary, Mr. Duncan, from the minutes of the Board showed how much attention and care the Board had expended on that important subject. Dr. Champneys then read out the following :—

> On February 25th, 1904, it was moved by Mr. Parker Young, seconded by Mr. Ward Cousins, and unanimously resolved : "That inasmuch as no provision is made in the Midwives Act, 1902, for the payment of legally qualified medical practitioners, the Government be requested to take the necessary steps for amending the Act, by introducing a section or otherwise, to provide for the payment of legally qualified medical practitioners when called in by midwives in difficult cases. Resolved further that a copy of this resolution be sent to the Privy Council. Resolved also that the secretary do include this resolution in the summary of the proceedings of the Board as supplied by him to the press."
>
> On November 24th, 1904, a letter was read from the hon. secretary of the Metropolitan Counties Branch of the British Medical Association inclosing a copy of a letter addressed by the branch to the London County Council, with accompanying pamphlet, and asking for the coöperation of the Board with the London County Council in obtaining powers from Parliament to pay registered medical practitioners when called in by midwives in emergencies. It was moved by Mr. Parker Young, seconded by Mr. Ward Cousins, and unanimously resolved : "That the hon. secretary of the Metropolitan Counties Branch of the British Medical Association be informed, (1) that this Board agrees that statutory provision should be made for the payment of the services of a registered medical practitioner when called in by a midwife in accordance with the rules of the Board ; (2) that the Board has already forwarded a resolution to this effect to the Privy Council."
>
> On July 26th, 1906, a letter was read from the clerk of the London County Council inclosing a copy of a letter from a certified midwife as to the payment of fees to medical practitioners when summoned in cases of emergency. Resolved : "That the London County Council be informed that the Board has repeatedly urged the amendment of the Midwives Act so as to provide for the payment of such fees, and that in some cases boards of guardians pay such fees where the poverty of the patient appears to justify such a course without insisting on the order of the relieving officer being obtained beforehand."
>
> On June 27th, 1907, the adjourned consideration of the report of the Midwives Act Amendment Committee was then proceeded with. Resolved : "That provision should be made for the payment out of public funds of reasonable fees to medical practitioners sent for in emergencies in accordance with the rules of the Board, with power to recover such fees from the patient or other person responsible, in suitable cases."
>
> On November 28th, 1907, a letter was read from Dr. W. P. T. Daniel, of 273, Cable-street, London, E., forwarding a copy of a resolution adopted at a meeting of medical men residing in the parish of St. George-in-the-East and neighbourhood, declaring their intention, after November 30th, not to proceed to any case of parturition, &c., occurring in the parish, on the requisition of a midwife, unless a minimum fee of one guinea is guaranteed either by the guardians or by the Central Midwives Board. Resolved : "(*a*) That a copy of the correspondence be sent to the Privy Council, pointing out the difficulties and dangers of the situation, and suggesting that a copy of the Local Government Board's circular on the subject, dated July 29th, 1907, should be forwarded to every medical practitioner in England and Wales. (*b*) That the Board's action in the matter be communicated to Dr. Daniel, and that he be informed that the Board has no power to pay fees in such cases."

The Privy Council had adopted the Board's suggestion that of two cases of pancreatitis with jaundice which I had the opportunity of investigating in Sir Thomas Fraser's wards in the Edinburgh Royal Infirmary. These cases were examined by me incidentally in the course of an extensive investigation into the clinical value of the pancreatic reaction in the urine (Cammidge). One of the cases was a patient with simple "catarrhal jaundice," the other was a case of malaria (malignant type) with jaundice. In each case a diagnosis of pancreatitis was made, from the association of (*a*) jaundice, (*b*) marked tenderness in the region of the head of the pancreas, and (*c*) a marked positive reaction in the urine by the pancreatic reaction. The results of my observations on these cases led me to conclude that the jaundice occasionally met with in malaria has its origin in pancreatic disease, and further that inflammation of the pancreas is an important factor in the development of simple "catarrhal jaundice." These views are in close accord with those expressed by Dr. Phillips, and in view of the clinical importance of the subject I have ventured to draw fresh attention to it.—I am, Sir, yours faithfully,

Edinburgh, March 22nd, 1908. CHALMERS WATSON.

THE STREAM HILL SANATORIUM SITE.

To the Editor of THE LANCET.

SIR,—In your issue of March 14th a letter appeared from Mr. Langley Brasier-Creagh, regarding the suitability of the Stream Hill site for a sanatorium for the county of Cork. As engineer appointed by the opposing ratepayers in the district of Buttevant and Doneraile to thoroughly examine the site and give evidence at the late Local Government Board inquiry I beg to say that, in my opinion, the site is utterly unsuitable for a sanatorium. The place is covered with patches of rushes, surface soil peat mould, and subsoil, most important of all, yellow marly clay, which is most retentive to moisture. Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Carlisle.—Commenting upon the Notification of Births Act, 1907, Mr. William Brown expresses the opinion that the Act, if adopted by the urban district council, can exert no beneficial effect unless provision for personal supervision by a trained staff of nurses is made. There is no doubt that this is quite a sound conclusion and apparently the Local Government Board is taking the view that its consent to the adoption of the Act should not be given unless it can be shown that good use is likely to be made of the information obtained; in other words, the Act is apparently to be used as a lever for the appointment of health visitors. There has been a remarkable reduction in the number of cases of enteric fever in Carlisle during recent years and Mr. Brown, who has taken much interest in the matter, attributes such reduction to the removal of private slaughter-houses, of ashpits, and of privies, and to general sanitary measures making for cleanliness.

Ilkley Urban District.—Dr. Augustus H. Bampton has not found the slop-closet method of excrement disposal satisfactory owing to the impracticability of keeping the upper portion of the closets clean. In some instances such closets are, he thinks, no better than the old-fashioned rural privy and he inclines to the view that they may have been instrumental in the causation of diphtheria; indeed, he goes so far as to suggest that the "general adoption of slop water-closets in towns may account for the incidence of diphtheria being transferred from the rural to the town district, the town district having practically adopted the former rural privy." We are afraid that slop-closets are not of sufficiently wide distribution in the country generally to render this explanation a very probable one. The infantile mortality in the district is a low one, the rate for 1907 having been only 88·5 per 1000 births and the average for the last ten years only 110 per 1000. The alleged cause of deaths was in the majority of cases either premature birth or congenital defects, neither of which are, Dr. Bampton thinks, preventable. Defective germ plasm cannot, he thinks, "be controlled by legislation. The fault is *ab initio*. There always will be addled eggs." As regards tuberculosis the medical officer of health suggests that this disease may be becoming less and less fatal owing to the fact that we are as a community becoming to a certain degree protected, possibly by repeated small doses of the bacillus.

Borough of Sutton Coldfield.—Dr. A. Bostock Hill refers in his current annual report to a case of diphtheria in which he regards the evidence as pointing to the conclusion that the disease was contracted from a cat which had been unwell before the patient showed signs of the malady. Later the cat became so ill that its destruction was considered advisable and upon some of the secretion from the throat being examined the diphtheria bacillus was detected.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8663 births and 5257 deaths were registered during the week ending March 21st. The mean annual rate of mortality in these towns, which had been equal to 17·6 and 17·2 per 1000 in the two preceding weeks, further declined to 16·9 in the week under notice. During the first 12 weeks of the current quarter the annual death-rate in these towns averaged 18·1 per 1000; the mean rate in London during the same period did not exceed 17·7. The lowest annual death-rates in the 76 towns last week were 8·8 in Great Yarmouth, 9·0 in Hornsey, 10·3 in York, and 10·5 in Aston Manor; the rates in the other towns ranged upwards to 25·0 in St. Helens and in Wigan, 25·2 in Bootle, 25·7 in Middlesbrough, and 27·6 in Hanley. The rate of mortality in London last week did not exceed 15·8 per 1000. The 5257 deaths in the 76 towns last week showed a further decline of 92 from the number in recent weeks, and included 409 which were referred to the principal epidemic diseases, against 414 and 400 in the two preceding weeks; of these, 151 resulted from whooping cough, 112 from measles, 62 from diphtheria, 38 fro diarrhœa, 30 from scarlet fever, and 16 from "fever" (principally enteric), but not one from small-pox. Th deaths from these epidemic diseases in the 76 towns wer equal to an annual rate of 1·3 per 1000, correspondin with the rate in each of the two preceding weeks; the rat from the same diseases in London did not exceed 1·1. N death from any of these epidemic diseases was registered la week in Leicester, Walthamstow, York, Devonport, Coventry or in eight other smaller towns; the annual death-rates fro these diseases ranged upwards, however, to 4·0 in Burnley 4·3 in Rhondda, 4·8 in Salford, and 6·6 in Warrington The fatal cases of whooping-cough in the 76 towns, whi had been 138, 149, and 134 in the three preceding weeks, rose to 151 in the week under notice; the highest death-rate. from this disease last week were 2·0 in Newport (Mon.), 2·3 in Sunderland, 3·0 in Wallasey, and 5·1 in Warrington The 112 deaths from measles were, however, fewer by 1 than the number in the previous week, but caused death rates equal to 2·0 in Burnley, 2·2 in Preston, 2·4 i Salford, 2·9 in Stockton-on-Tees, and 3·1 in Rhondda. Th deaths referred to diphtheria, which had been 66 and 58 i the two preceding weeks, rose again to 62 in the wee under notice; the highest death-rates from this diseas last week were 1·5 in Bournemouth, in Smethwick, and in Warrington. The 30 fatal cases of scarlet fever showed a decline of five from the number the previous week but included 11 in London, three Salford, and two in Birmingham, Birkenhead, and in Burnley. The 38 deaths attributed to diarrhœa exceeded those in the previous week by ten. Of the 16 deat referred to "fever" two were registered in London, in Liverpool, and in Leeds. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had steadily declined in the 15 preceding weeks from 5591 to 3429, had further fallen to 3356 on March 21st; 378 new cases were, however, admitted to these hospitals during the week under notice, against 345 and 312 in the two preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had declined in the five previous weeks from 481 to 317, rose to 320 in the week under notice, but were ten below the corrected average number in the corresponding week of the five years 1903–07. The deaths directly referred to influenza in London further declined last week to 68, from 141, 122, and 93 in the three preceding weeks. The causes of 60, or 1·1 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified last week in Leeds, Bristol, West Ham, Newcastle-on-Tyne, Hull, Salford, and in 48 other smaller towns; 14 uncertified causes of deaths were, however, registered last week in Liverpool, 11 in Birmingham, eight in Sheffield, four in Sunderland, and three in South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 19·3 and 20·3 per 1000 in the two preceding weeks, declined to 18·5 in the week ending March 21st, but exceeded by 1·6 the mean rate during the same week in the 76 large English towns. Among the eight Scotch towns the death-rates last week ranged from 14·6 and 15·2 in Edinburgh and Aberdeen, to 21·3 in Dundee and 22·2 in Perth. The 652 deaths in these eight towns showed a decrease of 62 from the number returned in the previous week, and included 84 which were referred to the principal epidemic diseases, against 96 and 97 in the two preceding weeks; of these, 37 resulted from measles, 24 from whooping-cough, 13 from diarrhœa, five from scarlet fever, three from "fever," and two from diphtheria, but not one from small-pox. These 84 deaths were equal to an annual rate of 2·4 per 1000, which exceeded by 1·1 the mean rate last week from the same diseases in the 76 English towns. The fatal cases of measles in the eight towns, which had been 47 and 46 in the two preceding weeks, further declined to 37 in the week under notice, and included 30 in Glasgow and five in Edinburgh. The 24 deaths from whooping-cough showed a further increase of four upon the numbers in recent weeks; 13 were returned in Glasgow, three each in Edinburgh, Leith, and Dundee, and two in Greenock. Of the in reply to the statements made against him, but he was shouted down. Mr. William McLeod then remarked that the parish council could dismiss a medical officer at any time without giving any reason, and went on to say: "A doctor is like a herd boy. You can dismiss him at any time by giving him notice." On a vote being taken five members voted in favour of Mr. Homer's dismissal and five against it. The chairman then gave his casting vote against the dismissal, which was the signal for a howl of disapproval and a chorus of violent protests. The disorderly incidents of this meeting and the threatening attitude of a large proportion of the parish council make it plain that a medical officer in the service of such a council must necessarily be a mere dependent, holding office under conditions which are hardly compatible with the position of a professional man. This system of providing medical advisers for sick paupers is evidently ripe for reform, and the Bill introduced in the House of Commons by Mr. Cathcart Wason, as mentioned in THE LANCET of March 21st, is a step in the right direction.

March 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Richmond Lunatic Asylum.

AT its monthly meeting on March 19th the joint committee of the Richmond District Asylum (Dublin) proceeded to the appointment of a resident medical superintendent in succession to the late Dr. Conolly Norman. At the meeting a report was submitted from a special committee of 21 members which had been appointed for the purpose of recommending changes in the staff consequent upon Dr. Norman's death. The resulting report included a minute to the effect that the vacant post should be filled by promotion from the staff and it was unanimously recommended that Mr. John O'Conor Donelan should be advanced to the position of resident medical superintendent, with the same authority and powers which had been given to the late resident medical superintendent, subject to the orders made by the joint committee regarding the responsibility of the various officers in connexion with the work assigned to them in their respective departments, and that Mr. Donelan's salary was to be fixed at £800 per annum, with house and other allowances estimated at £100 per annum. The committee further recommended that Mr. H. M. Cullinan, who had for many years been senior assistant at the Richmond Lunatic Asylum, should be promoted to the position of first medical officer at Portrane, at a salary of £600 per annum, with allowances similar to those given to Mr. Donelan. Some minor recommendations were also made regarding the subordinate members of the staff. The committee recommended no addition to the medical staff—making a special note expressive of a strong opinion "that the staff as now proposed ought to be sufficient to carry on the medical work of the institution, including annual leave." All the recommendations made were unanimous. The chairman, in moving the adoption of the report, after having referred in warm terms to the record of Mr. Donelan during the considerable number of years which he had spent in their service, pointed out that the readjustment which had been recommended by the special committee would effect a saving of nearly £600 per annum. The report was unanimously adopted.

Club (Contract) Practice.

Contract practice has not hitherto reached any considerable dimensions in Ireland, as it has done in the neighbouring island. Nor is it at all likely to as things go, either in the present generation or during the course of that next succeeding. There is, however, a somewhat similar arrangement in the club medical practice in Dublin, although this has not the wide prevalence of the analogous English growth which is now so characteristic of the large towns. Still, there exists a goodly proportion of club practice and club patients in the Irish metropolis, and the origin and survival thereof are due to very much the same source from which arises the crying evil of hospital abuse—the excess of professional supply over professional demand, with the jealousies and want of *esprit de corps* which flourish so readily in a profession of which the members can be subjected to no criterion of skill or attainments whereof the average public is qualified, as a body, to form anything approaching a just estimate. There are a good many clubs at present in Dublin the members of which pay an annual sum varying from 3*s.* to 5*s.* per annum, in return for which they receive medical and surgical advice, medical and surgical attendance at their homes, medical and surgical remedies and preparations required for the patient's use in every case of sickness, with medical, surgical, and obstetric advice, treatment, and medicine for all members of his family—in the case of every married member. It is, of course, quite superfluous to criticise the profit to either of the parties concerned in the fulfilment of this contract.

Epidemic Cerebro-spinal Meningitis.

It is announced that a special meeting of the Dublin corporation will shortly be held "to declare cerebro-spinal meningitis to be a notifiable disease for the period to the end of the 31st December, 1908, under the provisions of the Infectious Disease (Notification) Act, 1889." This is not due to any new or special apprehension. The conspicuously high death-rate of Dublin compared with that of the other large cities of the Empire makes the relatively easy escape which Dublin has had from cerebro-spinal meningitis a source of special satisfaction to the public health department for the conditions in Dublin have certainly been such as tended to make it a special focus of attraction for the germs of "spotted fever," a statement which is well borne out by the fact that the earliest description of "cerebro-spinal arachnitis" as a distinct clinical entity emanated from Dublin (in 1846).

Employers' Liability.

How very circumspectly employers must walk within the limits of the domain governed by the Employers' Liability Act has been sharply demonstrated by a decision that has just been given by the Recorder of Dublin. A gardener had had the sole of his foot penetrated to a slight depth by a dirty nail. Tetanus developed a few days afterwards and led to a fatal result. The bereaved widow sued the employer for damages under the recent Act of Parliament, and the latter had apparently not foreseen the almost boundless reach of the new law and had omitted the precaution to take out any inclusive policy of insurance. The Recorder, although apparently not devoid of sympathy with the employer's over-confidence, gave judgment in the widow's favour, with £150 damages, pointing out that the letter of the law absolutely forbade his taking any other course.

High Death-rate in Belfast.

For the week ended March 14th the death-rate from all causes was unusually high, 26·5, the mortality from chest affections alone being 12·3. The zymotic death-rate was only 1·9 and of this 1·5 was due to measles and whooping-cough, the death-rate for all the other infectious diseases being 0·4. There were on March 14th still 23 cases of cerebro-spinal fever in Purdysburn municipal fever hospital. It is a pity that the medical officer of health of Belfast attributes in his report the death-rate at present from chest affections in that city as being "entirely due to climatic conditions." This mortality was, as stated above, 12·3. Now at the same time in Edinburgh the total death-rate was only 17·3 per 1000 from all causes, and the climate of that city does not differ much from that of Belfast; indeed, most people who have lived in both places would say, from a chest point of view, that the climate of Edinburgh was the worse of the two towns. In 1862 the death-rate was from all causes in Edinburgh 25·88. In Belfast the latest returns give the death-rate from all causes as 26·5 and 12·3 from chest affections. What is the reason of the difference in the two places?

Queen's College, Belfast, Annual Dinner.

The annual dinner under the auspices of the amusements committee of the Students' Representative Council of Queen's College, Belfast, was held in the great hall on the evening of St. Patrick's Day, Dr. E. Letts (professor of chemistry) presiding. After the usual loyal toasts, Mr. A. B. Mitchell proposed "Queen's College, Belfast," pointing out the prominent part which it had played in the life of the country, to which the President (Rev. Dr. Hamilton) responded, saying that no matter what might befall the institution during the coming year they wanted room to do their work and to afford all classes of His Majesty's subjects, without distinction of creed or class, the benefit of a liberal education. Professor W. St. Clair Symmers proposed the toast of "The Queen's College Clubs and Societies," to which Mr. C. R. Crymble murmur, considering that in malignant disease and in some forms of phthisis in which the heart becomes atrophied *and not dilated* the so-called hæmic murmurs are absent. Now, however, the subject has been reconsidered by Balfour, MacAllister, Heitler of Vienna, and many others, and some of the interest hitherto monopolised by the valvular apparatus has been transferred to the state of the cardiac muscle and its nervous relations, with the result that it is now conclusively proved that dilatation *per se* apart from any purely valvular defects or abnormalities leads to regurgitation at the auriculo-ventricular orifices. ...... This condition, as long as it remains only slight and being associated with a normal physiological developmental process, naturally tends to repair or to a spontaneously favourable end. ...... Similar symptoms occur also later in life in adults, previously healthy, who have been subjected to unaccustomed forced exertion ...... these cases, in my opinion, are nearly always curable if they are treated rationally and with patience. No medicine is of the slightest use to obtain relief which can only be effected by providing a prolonged rest in the recumbent position for at least two hours in the middle of the day, so as to improve the muscular tone of the heart in allowing it to recover its exhausted energies and strength. ...... I submit a few practical points in determining the condition of the heart of the young adult, often a question difficult to decide accurately during the peculiar period of development at which it so often comes under our notice. In estimating the area of cardiac dulness choose the erect posture and the period of expiration. In the recumbent posture the intervening loose cellular tissue is not strong enough to keep the heart close to the sternum and ribs and preventing its receding by the force of gravity, and during inspiration either a large portion of lung may be brought in front of the heart, or the portion which is always in front of it may be so thickened by inflation as to thrust backwards for the time more of the heart than it actually covers. Even in the healthy heart the sound admits varieties in kind. A more clear sound proceeds from a thin heart and a duller sound from a thick heart; a sound of great extent from a large heart, of less extent from a small heart. Greater impulse is given by a thick heart, feebler by a thin one. Impulse is conveyed further from a large heart, to a shorter distance from a small one. The sounds and impulses mutually interpret each other. A clear sound indicates probability of an attenuated heart; joined to a weak impulse it becomes almost certain. A very strong impulse infers probability of an hypertrophied heart; joined with a diminished sound we argue its certainty. Impulse and sound increased together do not indicate hypertrophy, but forcible action from pure excess of nervous energy; impulse and sound decreasing together indicate defect of nervous energy, not atrophy. In persons of a nervous temperament the sounds of the healthy heart are of a high degree of intonation and acquire a greater audible extent under actual emotion far beyond the normal area. If I mistake not, after having examined nearly 8000 hearts in the past 15 months this condition is much more common in youths brought up in the bustle of great cities than in those of corresponding age reared in country districts. Never consider the sounds or impulse apart from the extrinsic circumstances which can so powerfully affect them. The condition of the diaphragm, of the abdominal cavity, the amount of adipose deposit in the superimposed structures, the configuration of the bones enclosing the thorax.

While recently doing a post-graduate course at St. Thomas's Hospital I think I heard Dr. Dyke Acland remark "that he had met somewhat similar conditions in lads from the public schools and that his treatment based on rest and modification of athletic exercises had been entirely successful." I am, Sir, yours faithfully,

THOS. E. H. WILLIAMS, F.R Hist.S.,
Deputy Inspector-General R.N. (retired).
Junior United Service Club, S.W., March 15th, 1908.

TANSINI METHOD FOR THE CURE OF CANCER OF THE BREAST.

To the Editor of THE LANCET.

SIR,—May I venture, with all respect for Italian surgery and its distinguished exponents Professor Tansini and Dr. Francesco Purpura, to criticise the Tansini method for the cure of cancer of the breast as described in THE LANCET of Feb. 29th. However ingenious, the method is not, I think, a reliable one because it fails to take into account certain facts of pathology. Save in regard to the precise shape of the area of skin removed, the method differs from that of Halstead only in the ingenious means adopted to cover in the raw area left by the operation. It has along with the merits the two capital defects of the Halstead operation. The first of these defects is that the area of skin removed is unnecessarily large, at any rate in the long axis of the oval portion ablated. The second defect is that no attempt is made to undermine the skin for the purpose of removing an extensive area of the deep fascia—a step which is absolutely essential on account of the proved fact that breast cancer spreads centrifugally by permeation of the deep fascial lymphatic plexus.

If only the moderate area of skin which is likely to be infected be removed, an area circular in shape and four or five inches in diameter, and if the skin flaps are undermined sufficiently to allow the removal of a possibly infected circle of deep fascia ten inches in diameter, it will be found in nearly every case that the long and mobile skin-flaps come together without any difficulty. The cutting of a large for transplantation, which must increase the severity duration of the operation, becomes quite unnecessary. F these reasons it appears to me undesirable that the method of flap transplantation should be used, save in exceptional cases. I am, Sir, yours faithfully,

W. SAMPSON HANDLEY.
Wimpole-street, W., March 14th, 1908.

ISOLATION HOSPITALS AND SCARLE FEVER.

To the Editor of THE LANCET.

SIR,—On June 8th, 1896, I wrote to you thus: "I that it has yet to be proved that the adoption of and the removal of every detected case to a fever have any material effect in lessening the prevalence spread of scarlet fever in London and what chance is th of stamping it out?"

I think that my sceptical forecast has been amply I read in THE LANCET of Jan. 4th, 1908, p. 42, that it w unanimously decided at a meeting of the Asylums Board "that in view of the continued prevalence scarlet fever, notwithstanding the extensive isolation modation provided, the Local Government Board be asked cause an inquiry to be instituted into the cause of the and whether any, and if so what, further means can adopted for its prevention." The further particulars added that the ratio of scarlet fever cases to population increased from 3·7 per 1000 in 1890 to 4·3 per 1000 in 19 Over £234,000 had been expended on sites and nearl £3,000,000 on building and equipment, besides a very amount, doubtless, on maintenance. Yet "for expenditure they were in no way better off from the of view of the spread of infectious disease."

I think that if inquiries were pushed still further matters of detail it would be found equally true, as I also, that patients are longer in recovering if treated in hospitals than if treated at home—ten weeks and instead of six weeks; and that cases of scarlet fever have better chance of recovery and avoiding complications treated at home. I have not seen any reason to alter opinion since then. Not only is it a grievous injustice the ratepayers to bear this heavy burden of expenditure but I believe that this indiscriminate charity does harm the recipients.

A passage in Lockhart's "Life of Sir Walter Scott" *apropos* and may serve as a warning: "And take care, [Sir Walter Scott] added, not to give them [the poor] any thing gratis; except when they are under the gripe of diate *misery*—what *they* think misery—consider it as a sin to do anything that can tend to make them lose their precio feeling of independence ......" This sound principle is, seems to me, habitually broken nowadays. Free education, free meals, free clothing, and free medical attendance for children, too abundant hospital treatment, old-age pensions, and other similar desiderata clamoured for by hot-headed Socialists cannot but tend to lessen this "precious feeling of independence." What the outcome of it will be the next few generations will show, but I do not think it will be satisfactory to the national welfare. I constantly see that there is no surer way of killing a patient than by (mistaken) kindness, and the same well-meant cause may produce wholesale moral ruin.

I am, Sir, yours faithfully,
F. LUCAS BENHAM, M.D., M.R.C.P. Lond.
Exeter, South Australia, Feb. 18th, 1908.

PANCREATITIS WITH JAUNDICE.

To the Editor of THE LANCET.

SIR,—In your issue of March 21st Dr. Sidney P. Phillips records an interesting case of pancreatitis with jaundice and acute parotitis in scarlet fever. In his comments Dr. Phillips states that "the case suggests a probable explanation of the jaundice occasionally occurring in scarlet fever, and incidentally, it may be added, it supports the contention that the so called 'catarrhal *jaundice*' is more often due to obstruction of the common bile-duct by the presence of an enlarged head of the pancreas than by thickened mucus within the duct." The probability of the correctness of this view has recently been demonstrated to me by observation advanced by three important observations, namely—(1) the discovery that syphilis might be communicated to the lower animals; (2) the discovery of the spirochæta pallida; and (3) the discovery of serum diagnosis, which might be performed by the method of agglutination or by the method of precipitation or by Wassermann's method of *Complementbindung*. The last mentioned was, in Dr. Citron's opinion, the oldest and most trustworthy method and its usefulness was ascertained by clinical observation. Necropsies of persons who had given a positive reaction invariably showed that they suffered from syphilis although there might be no obvious clinical symptoms. A positive reaction was a certain proof of syphilis but a negative one did not exclude it. The following principles to be observed in the treatment of syphilis might be derived from the new discovery. If a primary chancre was present together with spirochætæ and a positive serum reaction antisyphilitic treatment should be begun at once and not postponed till the appearance of constitutional symptoms. The same course should be followed where there was a positive serum reaction without spirochætæ. In the case of a negative serum reaction with spirochætæ the chancre should be excised and general antisyphilitic treatment adopted. If the serum reaction was negative and no spirochætæ were found in the supposed chancre no specific treatment was necessary but the test by serum diagnosis should be repeated subsequently.

The Treatment of Rabies.

The report of the rabies department of the Institution for Infectious Diseases quoted in the *Sachverständigen-Zeitung* states that in the year 1905 there were 234 persons treated for rabies by Pasteur's method and that four of them died. In 67·6 per cent. the diagnosis was made by inoculating animals from the patients, whilst in the remainder it was made from the clinical symptoms only. Of the total number of patients 94 had been bitten by dogs, whilst five had contracted the disease from other persons. Of these five patients three were medical men and one was an attendant at a dissecting-room who became infected at a post-mortem examination; two other medical men had been bitten by dogs and so were four veterinary surgeons, whilst nine of them had been infected at post-mortem examinations of animals. Local treatment was adopted for 115 patients only. According to observations made in the institution it is very difficult to destroy the virus in the wound, even a short time after the receipt of the injury, so that in every suspected case the Pasteur treatment should be used as soon as possible. The treatment consisted in injections of solutions prepared from dried medulla for 21 days; in severe cases a second series of injections was commenced a month later and continued for a fortnight. All the patients were treated as out-patients. The four who died came under treatment on the second, third, sixth, and eleventh days respectively, so that in the two former the treatment was begun in good time. Death was probably due in these instances either to the advanced age of the patient or to a very short period of incubation. In the two other cases the late beginning of the treatment was probably the cause of the fatal issue. One patient who did not return for treatment after the first injection died three weeks afterwards, probably from rabies. Deaths of persons without treatment came to the notice of the institution in six cases, death occurring from one to four months after the injury. From the opening of the institution in 1898 till April 1st, 1906, there had been 2900 persons treated with 25 deaths. If, however, those who died before the end of the treatment or within two weeks afterwards were deducted the number of deaths is reduced to 13, giving a mortality of 0·448 per cent.

The Etiology of Psoriasis.

At a meeting of the Berlin Medical Society Dr. Nagelschmidt read a paper on the Connexion between Psoriasis and Affections of the Pancreas. He said that psoriasis was probably the result of a diathesis and there seemed to be a connexion between it and diabetes, for psoriasis was rather frequent in diabetic patients and conversely glycosuria was often present in sufferers from psoriasis. At a necropsy of a diabetic patient affected also with psoriasis he found cirrhosis of the pancreas. He accordingly prescribed pancreatin in psoriasis, the result being that eight out of 13 patients either recovered or were considerably relieved. Pigmentation of the skin remained after the treatment. Good results were, however, also obtained by the administration of an extract of the thyroid gland and of the testicle.

March 23rd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

A Department of Health for Canada.

SIX years ago, in 1902, at the Montreal meeting of the Canadian Medical Association, a resolution was unanimously passed calling on the Dominion Government to consolidate the various medical services of the Dominion into one department under one of the existing Ministers of the Crown. Year after year that resolution has been reaffirmed at the annual meetings and a special committee on public health has repeatedly urged upon the Federal Government the feasibility and desirability of the proposition. As matters now stand the various medical services are scattered over five different departments, often necessitating confusion and much delay in health matters. On March 3rd the special committee on public health, accompanied by the medical members of the House of Commons and the Senate, waited on the Prime Minister and his colleagues. The way was open for a free discussion and presentation of the subject, as there had been held in the House of Commons an interesting debate on the subject on a motion introduced by Dr. Black, M.P., Windsor, Nova Scotia. Dr. Lachapelle, chairman of the Board of Health of the Province of Quebec, presented a memorandum on behalf of the association which, in addition to setting forth the above desired object, also called upon the Government to establish, equip, and maintain a national laboratory for the examination of vaccines, sera, &c. Addresses were delivered by Dr. Lachapelle, the convener of the special committee; by Dr. R. W. Powell, Ottawa, who had been for five years the convener of this committee; by the general secretary of the Canadian Medical Association, Dr. George Elliott, Toronto; by Dr. Schaffner, M.P., Manitoba, and by Lieutenant-Colonel Carleton Jones, M.D., Director-General of the Canadian Army Medical Services. In reply thereto the Premier, Sir Wilfrid Laurier, and the Hon. the Minister of Agriculture considered the plan a feasible one but that there might be some difficulties in the way. The matter is to come up for fuller debate later in the House of Commons.

Annual Report of the Provincial Board of Health, British Columbia.

In presenting his eleventh annual report, that for the year 1907, Dr. C. J. Fagan, the secretary of the Board of Health for the province, states that it is a better one than that of the previous year. On the subject of small-pox he stated that the disease had been present during the year in nine centres with 38 cases in all. In almost every instance the trouble was imported from the United States. He referred to bubonic plague, which had also appeared in the State of Washington, yet had gained no foothold in British Columbia. This probably has been due to the fact that British Columbia has established a laboratory for diagnostic purposes with Dr. Bapty in charge. Dr. Fagan states that the infection has been present in San Francisco for the past seven years and that it has spread to six or seven other places in the State of California. A point which has been established in British Columbia is that the rat flea is not the same as is found in England but is the true India rat flea. It has been further found, and this is contrary to English views, that the pulex cheopis infests both the brown and the black rat. Dr. Fagan refers at length to the medical inspection of schools and strongly recommends that public school teachers should qualify to impart instruction in sanitary science.

Conference on Tuberculosis in Ontario.

A conference on tuberculosis was held in Toronto on March 4th, having been convened at the instance of the National Sanitarium Association. His Excellency the Governor-General came from the capital to preside. Delegates were present from 44 municipalities of the province and from 17 counties. By a unanimous vote a motion was carried calling on the Ontario Government to increase the grants for the stamping out of tuberculosis throughout the province. Mr. W. J. Gage (Toronto), the founder of the National Sanitarium Association which now administers four sanatoriums, two in Muskoka and two at or near Toronto, delivered an address. In the course of his remarks he stated that the Ontario board of health returns for the past ten years showed that there had been over 30,000 deaths in the province from tuberculosis. There was encouragement in the fact that in the past seven years there being able to visit the day nursery, to tend the infants there, and to consult with the matron. An urgent appeal is made to the charitable for funds to carry out this worthy object.

Warrington Infirmary Extension: Opening by Lord Cross.

The new extension to the Warrington Infirmary, which has been erected at a cost of £15,000, was opened on March 21st by Viscount Cross, G.C.B., in the presence of a large gathering of townspeople. The new block of buildings comprises a pavilion three storeys high, consisting of three wards, each ward containing 22 beds, and a nurses' home affording accommodation for 25 nurses. The growing requirements of the town have been of such a nature that an extension of the present building was deemed necessary. Towards the cost the sum of £14,913 has already been raised and it is confidently anticipated that the remainder will be shortly forthcoming. Lord Cross arrived at the town hall shortly after one o'clock, when he was met by the mayor and the representatives of the infirmary. A procession was formed, headed by the Volunteer band, and proceeded to the main door of the building. On arrival Sir Gilbert Greenall, Bart., invited Lord Cross to open the new extension and presented him with a gold key suitably inscribed. Lord Cross, who met with a warm reception, said that in the year 1877 he had had the honour of laying the foundation-stone of increased buildings to the infirmary. They had again given him the pleasing duty that day to do something towards further buildings. In the first place, one could readily see how the town and neighbourhood had increased in prosperity. The works had grown and the population had grown also. As the population had grown the cares and needs of the infirmary had increased. Although since 1877 a considerable addition was made it was found necessary to provide further accommodation. In 1677 there were only 87 in-patients, 948 home patients, and 1992 out-patients. The figures last year showed that there were 607 in-patients, 1441 home patients, and 3652 out-patients. Those increased figures made it quite clear that a want existed. He had great pleasure in declaring the building open. A tour of the buildings was then made by the visitors, after which luncheon was served in the drill-hall.

March 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Retirement of Sir Henry D. Littlejohn.

THERE has been a rumour current for some weeks that Sir Henry D. Littlejohn contemplated resigning the public offices which he has so long held. It is now known that he has tendered his resignation to the Edinburgh town council as its medical officer of health and as police surgeon. Two years ago he resigned the professorship of medical jurisprudence in the University after occupying the chair for ten years. As Sir Henry Littlejohn was born in 1828 everyone will feel that he is well entitled to relief from the strain of official duties and responsibilities. The two public offices mentioned have been held for 46 years, 1862 having been the year of his appointment to both. His term of office thus covered a period marked by great advances in sanitary science and the practical application of these by local authorities. It was his report on the sanitary condition of the city—one of the first things which he was called upon to do on his appointment in 1862—which led to the scheme for the improvement of the slum districts in the city and which has been carried out on an extensive scale. It was during the early years of his tenure of office that the Vaccination Act was applied to Scotland. It was also during his time that the city authorities provided a hospital for the reception and care of infectious cases first in the old Royal Infirmary buildings and later in the modern and well-equipped hospital at Colinton Mains. Before he occupied the chair of medical jurisprudence in the University he had for many years been a popular lecturer on the same subject in the extra-mural school. In addition he was medical adviser to the Local Government Board and to the Crown in Scotland in criminal cases. He was thus employed in all the great criminal trials of the past 60 years; indeed, as a medical expert he had a large practice and was a well-known figure in Parliament House. In 1895 the late Queen conferred on him the honour of knighthood. Although Sir Henry Littlejohn has wisely decided to curtail his activities he still shows a physical an a mental alertness that might well be envied by younger me and which will enable him to continue to interest himself i the various works of beneficence which he has alway encouraged by his presence.

Royal Edinburgh Hospital for Sick Children.

The forty-ninth annual general meeting of those intereste in this hospital was held on March 18th. The annual repo showed that during the year 1907 2348 children had bee treated in the wards. Of this number 534 were infant under one year. The average daily number of patients wa 100. In the out-patient department 27,070 had been treatec The number of operations performed in the surgical theatr was 798, while minor operations in the out-patient depart ment numbered 1361. The convalescent home had proved most valuable adjunct to the hospital. The cost of carryin on the home had been £477. The ordinary income of th hospital was £6374, while the ordinary expenditure wa £8475. The legacies received during the year amounted t £4895. The medical staff urges the need of a more adequat convalescent home and also of increased balcony accommodation in connexion with the wards.

The Medical Education of Women in Edinburgh.

The close of the winter session has been marked b some excitement amongst the women students of medicin in Edinburgh the cause of which will be dealt with n week.

The "Enteric Carrier."

A striking example of an "enteric carrier" and the damag that he or she may unwittingly do is brought to light in th report of the city bacteriologist on his work in connexio with the recent epidemic of enteric fever in the west-end o Glasgow. At one farm where investigations were carried ou the investigators failed to obtain any enteric bacilli by examination of the dairy vessels, the drains and surroundings of the steadings, or the milkers—with one exception This exception was an elderly woman who had suffered fro enteric fever 16 years before, and bacteriological tests showe that she was still infective. The source of infection a this farm appears to have been responsible for the first eigh cases, including that of the farm patient whose illness was a first diagnosed as pneumonia. This last patient, it will be remembered, was nursed for some time in the farm kitchen and she was apparently directly responsible for the spread o the outbreak in Glasgow. A danger of missed diagnosis, however, as in that case is one easily understood and one that can be combated by compulsory notification of any illness occurring in a farm supplying milk to the public. It is a much more alarming state of matters if one has to bear in mind the possibility of an epidemic being started by farm workers or dairymen who at some far remote period of their lives have suffered from enteric fever.

The Tenure of Office of Scottish Poor-law Medical Officers.

The unsatisfactory state of the law with regard to tenure of office by Poor-law medical officers in Scotland is a frequent subject of comment in THE LANCET and a remarkable example of the mischievous effects of the present system is published in a recent issue of the *John o' Groat Journal*. On the extreme north coast of Scotland there is a parish called Farr in the county of Sutherland. It has an area of about 188 000 acres with a population of about 2000 persons. Since 1903 the Farr parish council has had five medical officers. Three of those have been dismissed and another left suddenly. The present holder of the appointment, Mr. Thomas Homer, who has now been more than two years in the parish, has incurred the hostility of a section of the council and a motion for his dismissal was discussed at a meeting of that body held on Feb. 11th. According to the published report the proceedings formed a scene of almost continuous uproar and altercations. After Mr. Homer's dismissal had been duly moved and seconded a deputation came forward headed by a Mr. Donald Mackay who in stirring language made accusations against the officials of the parish charging them with endeavouring to take sole control of the parish business. He declared that he was going to fight for the interests of the parish while he had a breath left in his body. Several petitions were then produced by Mr. Mackay. One of these had reference to the "intolerable position" which had been created "owing to the doctor not working harmoniously along with the nurse," and several speakers made various charges against Mr. Homer. Mr. Homer in his turn several times appealed to the meeting for a hearing

Forensic Medicine.—G. K. Aubrey, King's College Hospital; and A. H. Turner, Leeds.

Midwifery.—V. P. Norman, Durham; H. T. Roberts, St. Mary's Hospital; and A. H. Turner, Leeds.

The diploma of the Society was granted to the following candidate, entitling him to practise medicine, surgery, and midwifery:—A. H. Turner.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Heinrich Grabower has been appointed Professor of Laryngology.—*Budapest:* Dr. Michael Horvath has been recognised as *privat docent* of Orthopædic Surgery.—*Copenhagen:* Dr. Axel Trolle has been recognised as *privat-docent* of Gynæcology.—*Göttingen:* Dr. Heit Müller, Lecturer on Odontology, has been granted the title of Professor.—*Halle:* Dr. Mohr of Berlin has been appointed Extraordinary Professor of Medicine and Director of the Medical Policlinic.—*Jena:* Dr. Wilhelm Busse has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Leipsic:* Dr. Hieronymus Lange has been appointed Extraordinary Professor of Children's Diseases. Dr. Richard Seefelder has been recognised as *privat docent* of Ophthalmology.—*Odessa:* Dr. Joseph Pozbariski has been recognised as *privat-docent* of Pathological Anatomy.—*Pavia:* Dr. Alberto Ascoli has been recognised as *privat-docent* of Physiological Chemistry.—*Prague (German University):* Dr. Eduoard Pietrzikowski has been appointed Extraordinary Professor of the Surgery of Accidents.—*Rome:* Dr. Ugo Lombroso has been recognised as *privat-docent* of Physiology.—*Rostock:* Dr. Johannes Müller has been appointed Extraordinary Professor of Physiology and Dr. E. Schwalbe of Karlsruhe, Professor of Pathology and Director of the Pathological Institute, in succession to Professor Thierfelder. Dr. E. Martini has been recognised as *privat-docent* of Anatomy.

SANATORIUMS FOR TUBERCULOSIS.—There was a large attendance of delegates from the various boards of guardians in Somerset at a conference held at Wellington on March 17th. Dr. J. Meredith read a paper entitled "The Provision of a County Hospital for the Treatment of Consumption," and after some discussion it was unanimously resolved that it was not desirable to provide a county hospital for this purpose.

COMPLIMENTARY DINNER TO SIR MALCOLM A. MORRIS.—An interesting dinner party took place on March 19th, at the Imperial Restaurant, Regent-street, London, when a number of the friends and colleagues of Sir Malcolm Morris, K.C.V.O., desiring to tender their congratulations on the honour recently conferred upon him by His Majesty, determined that a suitable occasion would arise while entertaining him as their guest. A party was therefore arranged numbering 35, including Mr. Frederick Morris, one of the sons of the guest of the evening. Dr. H. Radcliffe Crocker was in the chair. During the course of the evening, and after the King's health had been duly honoured, the chairman proposed the toast of their guest. He spoke of the friendly relationships which had existed for so many years among those especially interested in the study of dermatology in this country. In this connexion he referred to the good work done during the period of its existence by the Dermatological Society of London, now included in the Royal Society of Medicine. The result of the work of this society had been, he said, to advance the collective study of cutaneous diseases to an extent unequalled by any other agency, while it had fostered the growth of friendship among its members, of whom Sir Malcolm Morris had been one of the original. He then referred to the influence exerted in the advance of dermatology by Sir Malcolm Morris and to the high position which he occupied in the medical world generally, evidence of which was now clearly given by the recent gracious action of the King in knighting their guest. Dr. Crocker concluded by congratulating Sir Malcolm Morris "as a valued professional colleague and an esteemed friend, on behalf of all those present, upon the high honour conferred upon him by His Majesty." In his reply Sir Malcolm Morris referred to the growth and recent developments in the study of cutaneous medicine and to the valuable influences which had been exercised by the old Dermatological Society. The work of every one of its members had been laid before the others for criticism and for mutual instruction. It deserved in a special sense the epithet of a "College of Dermatology." He made mention in cordial terms of the peculiarly harmonious character of the comradeship of the members, adding that while he appreciated in the highest degree the personal character of the honour conferred upon himself, he preferred to look upon the King's act more from the point of view of a recognition of the position gained for dermatology as a branch of scientific medical study in this country than as a purely personal Royal favour. Dr. J. Mitchell Bruce proposed the health of the chairman in cordial terms, so bringing an interesting meeting to a conclusion.

THE PROPOSED UNIVERSITY FOR BRISTOL.—Sir F. Wills has again contributed £5000 to the fund for establishing a university in Bristol. This brings his contribution up to £10,000 and will found a chair in the new university.

MEDICAL MAGISTRATES.—The names of Mr. David John Thomas, M.R.C.S. Eng., L.R.C.P. Edin., of Nantymoel and Mr. Daniel Jenkins Thomas, M.D. Brux., L.R.C.P. Lond., M.R.C.S. Eng., of Bargoed, have been added to the commission of the peace for the county of Glamorgan.

NEW ISOLATION HOSPITAL.—The new small-pox hospital which has been erected for the Barry district in Glamorganshire at a cost of £4624 has just been completed. The cost of the building and maintenance is borne equally by the Glamorganshire county council and the Barry sanitary authority.

VACCINATION FEES.—For some months past vaccination has not been carried out by the Launceston board of guardians. The guardians adopted the reduced minimum fee of 3*s.* 6*d.* per case, and as the public vaccinators refused to accept these terms they were given notice to terminate their contracts and the matter was referred to the Local Government Board. At the last meeting of the guardians a letter was read from this authority stating that the fees should be as formerly—viz., 5*s.*, with the exception of the town of Launceston, in which the fees should be 3*s.* 6*d.*

ROYAL MICROSCOPICAL SOCIETY.—Lord Avebury, President of the Royal Microscopical Society, delivered the presidential address at a meeting held on March 18th. At the commencement of his discourse, which was entitled "On Seeds, with special reference to British Plants," he said that he would confine himself that evening to dicotyledons and that on the corresponding occasion next year he hoped to discuss the conifers and monocotyledons. He then proceeded to discuss various methods by which seeds were dispersed round the parent plant or conveyed to a distance or otherwise placed in conditions suitable for germination. Many seeds and fruits, he said, were provided with hooks which adhered to the bodies of passing animals, many seeds had downy attachments which enabled them to be carried by the wind, and many seeds were contained in elastic capsules which at the moment of bursting projected their contents to a considerable distance. Lord Avebury had made careful observations of the elastic capsules of the common wild *Geranium Robertianum* and had found that they could throw the seeds for a distance of 25 feet. Some capsules appeared to present phenomena of mimicry, simulating edible berries and caterpillars. Birds therefore picked them from the parent plant but after carrying them some distance discovered the deception and let them fall to the ground where they eventually germinated.

THE MEDICAL INSPECTION OF CHILDREN IN WEST SUSSEX.—There is ample evidence already that the duties imposed upon education authorities under Section 13 of the Education (Administrative Provisions) Act of 1907 will not be perfunctorily performed in West Sussex. The actual work has been commenced, much good has resulted, and if anything is necessary to show the great need of the new regulations is the fact that in one school alone the percentage of needy cases was as high as 50. The principal defects reported were defective eyesight, adenoids, and enlarged tonsils. It is felt that in many cases it will be necessary that there should be some agent, as it were, between the medical officer and the parents who would drive home to the parents the seriousness of the defects which have been found, their responsibility in the matter, and the advantage not only to the children but to themselves of having those defects remedied. And more particularly is the need of such an agent felt necessary in the cases of the poorest of the poor who are quite unable to bear any expense. In such cases the agent would be the means of securing hospital letters and the wherewithal with which the parent could take the child to a hospital or infirmary, perhaps many miles distant. The chairman of the West Sussex education

(President of the Students' Representative Council) replied. Dr. J. W. Browne proposed "The Chairman," to which Dr. Letts replied.

March 24th.

PARIS.
